## PS11036

### INTEGRATED FUNCTIONS AND FEATURES

- Converter bridge for 3 phase AC-to-DC power conversion.
- 3 phase IGBT inverter bridge configured by the latest 3rd generation IGBT and diode technology.
- Inverter output current capability  $I_O$  (Note 1):

Type Name	Motor Rating	$I_O$ (100%)	$I_O$ (150%; 60sec)
PS11036	2.2 kW/200V AC	11.0Arms	16.5Arms

(Note 1) : The inverter output current is assumed to be sinusoidal and the peak current value of each of the above loading cases is defined as :  $I_{OP} = I_O \times \sqrt{2}$ ,  $T_c < 100^\circ\text{C}$

### INTEGRATED DRIVE, PROTECTION AND SYSTEM CONTROL FUNCTIONS:

- P-Side IGBTs : Drive circuit, high-level-shift circuit, bootstrap circuit supply scheme for Single Control-Power-Source drive, and under voltage (UV) protection.
- N-Side IGBTs : Drive circuit, DC-Link current sense and amplifier circuits for overcurrent protection, control-supply under-voltage protection (UV), and fault output (Fo) signaling circuit.
- Fault Output : N-side IGBT short circuit (SC), over-current (OC), and control supply under-voltage (UV).
- Inverter Analog Current Sense : N-Side IGBT DC-Link Current Sense.
- Input Interface : 5V CMOS/TTL compatible, Schmitt Trigger input, and Arm-Shoot-Through interlock protective function.

## APPLICATION

Acoustic noise-less 2.2kW/200V AC Class 3 phase inverters, motor control applications, and motors with built-in small size inverter package

**INVERTER DC-LINK IGBT CURRENT ANALOGUE SIGNALING OUTPUT (TYPICAL)**

(Fig. 4)

**CURRENT ABNORMALITY PROTECTIVE FUNCTIONS**

(Fig. 5)

Protection is achieved by monitoring and filtering the N-side DC-Bus current. The over-current protection is activated (after allowing a filtering time of 10  $\mu$ s) when the line current reaches 250% of the rated load-current  $I_O$  (rms). Similarly, the short circuit protection is activated (after allowing a filtering time of 2  $\mu$ s) when the line current reaches twice the rated collector-current ( $I_C$ ). When a current trip-level is exceeded (OC or SC), all the N-side IGBTs are intercepted (turned OFF) and a fault-signal is output. After the fault-signal output duration (1.8 ms - typ.), the interception is Reset at the following OFF input signal. However, since the fault may be repetitive, it is recommended to stop the system after the fault-signal is received and check the fault. The trip-level settings described above are summarized in the following figure:

**ARM-SHOOT-THROUGH INTER-LOCK PROTECTIVE FUNCTION**

(Fig. 6)

**Description:**

- (1) During the ON-State of either of the upper-arm or the lower-arm IGBT, the inter-lock protection circuit blocks any erroneous ON pulses (resulting from input noise) from triggering the other arm IGBT and thus it prevents the arm-shoot-through situation.
- (2) When two ON-signals are received for both the upper and the lower arms, the signal received first will be passed to the IGBT and the second signal will be blocked. The second signal will be passed to its corresponding IGBT immediately after the first signal is OFF.

**Note:** This protective function provides no fault signaling output. The Dead-Time has to be set using the micro-controller (CPU).

**Operation:**

- a1. P-side normal ON-signal  $\Rightarrow$  P-side IGBT gate turns ON.
- a2. N-side erroneous ON-signal  $\Rightarrow$  N-side IGBT gate remains OFF.
- a3. While P-side ON-signal remains  $\Rightarrow$  P-side IGBT gate remains ON.
- a4. N-side normal ON-signal  $\Rightarrow$  N-side IGBT gate turns ON.
- b1. N-side normal ON-signal  $\Rightarrow$  N-side IGBT gate turns ON.
- b2. Simultaneous ON-signals  $\Rightarrow$  P-side IGBT gate remains OFF.
- b3. N-side receives OFF-signal  $\Rightarrow$  N-side IGBT gate turns OFF.
- b4. Immediately after (b3)  $\Rightarrow$  P-side IGBT gate turns ON.
