Description

1. Description

The MCBL 5004 and the MCDC 5004 are very compact motion controllers ideal for our brushless DC-Servomotors and brushed DC-Micromotors.

FAULHABER

Each model comprises a PWM servo amplifier.

Technology

Both motion controllers are based on a fast, powerful 16 bit microcomputer system.

This guarantees high dynamics, precise positioning and quiet running, regardless of the motor type used.

The well thought-out design and consistent application of SMD technology ensures a very compact device. The specially developed user software offers high flexibility and simple handling.

Application field

Developed with the use of state-of-the-art technology, the motion controllers are suitable for a wide range of applications: insertion and handling machines, machine tools, robots, X/Y tables, drive and automation systems in medical technology, chemical and food industry, etc.

Programming

One of the most important objectives in the development of these units was to keep its operation as simple as possible. This has been attained with the use of just a few, highly efficient functions.

Manual balancing or potentiometers are no longer required. Menu-guided program and parameter-editing functions are already integrated for operation with an ASCII terminal. In place of internal menu management, the clearly structured command set can be simply integrated into a customer-specific interface, e.g. with Visual Basic, Lab View, Pascal, C++, etc.

Any PC with Windows operating system can be used as an input terminal. Program up-dates are made directly via the serial interface without changing the hardware.

Communication is made via the serial port RS232 or RS485.

- 2 Power supply
- ③ Encoder¹⁾
- ④ Input for special function
- 5 Digital Input / Output

¹⁾ Line driver encoders for noisy environments or long distances can be used.

5

Start-up procedure

5. Start-up procedure

Here we list a step-by-step start-up procedure for both the electrics and software. Also included are several examples in order to allow the user to test the unit and familiarise himself with programming.

We therefore recommend that this sequence is followed for trouble-free installation:

FAULHABER

Start-up Procedure for MCBL 5004

- Connect the motor phases to MOTOR
- Connect the encoder and the motor Hall sensor leads to ENCODER HALL
- Connect the RS232 (or RS485) to the computer port COM1
- Connect the power supply to PWR
- Power the motion controller
- Software start-up

Start-up Procedure for MCDC 5004

- Connect the motor terminals to MOTOR
- Connect the encoder to ENCODER
- Connect the RS232 (or RS485) to the computer port COM1
- Connect the power supply to PWR
- Power the motion controller
- Software start-up

The computer link is necessary to program the motion controller. After programming has been completed, the computer link can be disconnected since the programs can be started using the motion controller input functions.

For advanced functions such as:

- Analogue input command
- Stepper motor emulation
- Second encoder input
- RS 485 serial interface
- Multi-axis operation

please refer to the specifique chapters

Start-up procedure

7

Start-up procedure

PLC I/O description

The PLC I/O port enables direct communication with the position control function without having to use a computer. For example, once a program has been created, it can be executed by simply giving a command to the assigned input. In the initial phases of installation, and to allow the user to better understand the operation of the motion controller, all instructions are given via computer. It is therefore not necessary to connect this port.

RS232 description

This port is the communication link between the motion controller and the external computer via the COM1 connection point. Additional information regarding the connection and set-up is given in chapter 32. The link is make with a standard computer cable which, if necessary, can be optionally supplied by Minimotor.

Start-up procedure

8. Software start-up

The diskette supplied with the motion controller contains:

installation program

program MCxx_yyy.S19 (basic motion controller software)

terminal emulator for Windows

program MM_WIN.TRM with the pre-defined terminal emulator parameters

To copy the software onto your hard disk using Windows, first of all start the installation program from the DOS prompt which copies the contents of the diskette into a directory MIMO_MC which is automatically created. You should now work only on your hard disk.

The diskette now serves as a back-up for security purposes only.

- Go to the MIMO_MC directory and open the file TERMINAL.EXE.
- Go to FILE menu and open MM_WIN.TRM.
- Press MENU button on the screen. The following menu will appear:

🛃 T	ermin	al - MM_	WIN.TF	₹ M				_	
<u>F</u> ile	<u>E</u> dit	<u>S</u> ettings	<u>P</u> hone	<u>T</u> ransf	ers <u>H</u> elp	S.			
	MI	NIMC	TOR	SA	MCxx	500	4		
		S	ET U	JP V	ALUES	, ,			
\$`		С	N LI	INE	CONTE	lOL			
		P	ROGI	RAMM	1ING				
		Ε	TIX	MEN	1U				-
•									▶
			<u>}</u>				2		

As a check, the motion controller 7-segment display should show 0 (zero).

If this does not happen, you should first check all the connections. If the above menu still does not appear on the screen, you should re-install the software program MCxx_yyy.S19. Instructions for this procedure can be found in chapter 28.

At this point, the start-up procedure is complete. The unit is now ready to be programmed for its specific application.

FAULHABER

General software information

Terminal emulator description

The computer is only used as a terminal. The terminal emulator therefore enables communication between the computer and motion controller software. The actual programming is made directly in the motion controller itself.

Motion controller software organisation

The software is constructed on three different levels.

Operating system

The operating system normally remains invisible to the user and is a background function for:

- download functions
- back-up in emergency situations

For additional information, see chapter 28.

Program MCxx_yyy.S19

Is the basic working program which realises all described functions and programming possibilities. This program is already installed within the unit and automatically goes into operation once the system is started-up. Actualy version 3.40

Application user programs

Contains the complete set of customer-defined data and parameters (= "application").

Display	Description
0	Device active, Servo amplifier OFF
1	Servo amplifier ON, closed loop system active, ready for motion
F	Operating system active
xx blinking	xx error code, see chapter 27

7-segment display status

General programming instructions

General instructions on how to move, insert, delete, etc. within the program:

- Close every entry with the command <ENTER>
- Text can be entered using either small or capital letters
- Use the arrows to move up and/or down the menu lines
- To go back to the previous menu always use <ESC>
- Close erroneous entries with <ENTER> and re-enter data

Delete characters Clear line Insert line Page down Page up Back Space <CRTL C> <CRTL I> <CRTL D> <CRTL U>

Set up values

9. Pre-defined set up values

The SET UP VALUES menu contains all the necessary parameters for the unit to function according to the specific application.

The motion controller has default parameters which allows it to run the majority of motors stably, allowing the user to fine-tune the unit's operation without the risk of causing damage.

FAULHABER

For optimum operation it is of course necessary for the individual parameters to be set according to the requirements of the specific application. A description on how to optimise the system is contained in chapter 11.

As an initial step the user should familiarise himself with the motion controller instructions which are available via the ON LINE CONTROL menu. As we will see later, it is important to first get the motor running before optimising the parameters.

Attention!

Before giving any instructions to the motor, ensure that it is first running without load since the current limiter is not set to the maximum motor current.

WAY	Way in lines (relative) for RR and RW instructions
POSITION	Position in lines (absolute)
WAIT REPEAT	Wait time for RR and RW instructions

Parameters graphic explanation (example with RW)

Encoder resolution

Using the two encoder channels, the motion controller internal electronics multiply the encoder resolutions by 4. For example, when using a 500 line incremental encoder, one revolution of the motor shaft corresponds to 2 000 lines. Therefore WAY 2 000 corresponds to one motor shaft revolution.

Acceleration and deceleration

When setting the acceleration, the system automatically sets the deceleration to the same value.

Set-up values

11. System parameter set-up

Current limiter set up

The current limits I NOM and I PEAK must be set according the motor used. The value of I NOM should not exceed the motor's recommended current for continuous operation.

FAULHABER

I NOM limit is only active during constant speed operation.

I PEAK limit is only active during acceleration and deceleration.

There is a continuous monitoring of incremental feedback. If the motor is blocked more than 0,5 seconds then the current will be automatic reduced.

Optimising the closed loop parameters

The closed loop system can be optimised by running the motor (including assembled mechanical parts) directly on line and by adjusting the following parameters via the SET UP VALUES menu:

PROPORTIONAL	(1 - 50)
INTEGRAL	(0 - 50)
DERIVATIVE	(1 - 50)
VELOCITY	(1 - 50)

This optimisation is best carried out by running the motor with the RW and/or RR instructions.

When executing these instructions, all parameters (even set-up) can be changed on line, thus enabling the user to see the reaction of the system whilst making changes. One helpful function is the EC (encoder counter) which gives information on the actual motor shaft position.

Improved dynamics

If your application requires more dynamics, this can be obtained by increasing the PROPORTIONAL, DERIVATIVE and VELOCITY LOOP values (e.g. to 10, 20 and 20). If the motor is noisy or vibrates (indicating system instability), these parameters should be reduced.

Precise positioning

If you need to improve the motor's position holding, an INTEGRAL value should be given (e.g. 5). The INTEGRAL value is only activated when the motor reaches the requested position. In this way the system's dynamic is not influenced by this value.

To control the exact position of the motor, the EC (encoder counter) command is used via the ON LINE CONTROL menu.

Programming

12. Programming

Here we look into the individual PROGRAMMING menus of the system. Practical examples of how the motion can be controlled are to be found at the end of this section.

12.1 Home function

This is the fixed reference starting (home) position. The home command can be given whenever the system should return to the home position.

Programming

DIR_H 🔬	Direction of rotation to go to external sensor
SPE_H	Speed for finding external sensor
INP_H	Assign external sensor input
DIR_Z	Direction of rotation to go to encoder Z index
SPE_Z	Speed for finding encoder Z index
CLR OUT	Clear all outputs after HOME

The home function runs from line 1 through line 5 and can be executed using either an external sensor or the encoder Z index. Therefore, for example:

If the home function is executed using an external sensor, lines 4 and 5 are set as follows:

FAULHABER

0
0

If the home function is executed using the encoder Z index, the first 3 lines are set as follows:

DIR_H	0
SPE_H	0
INP_H	0

For an extremely precise home position use first the external position sensor and then the encoder Z-index. In this case all 5 lines in the home function menu must be set.

There is also a possibility to set the home function without using either an external sensor or the encoder. Only in this case <u>all parameters are set to zero</u> and the system's position at the time of executing home is considered the home position.

To complete the home function you can also define if the digital outputs should be cleared or not (CLEAR OUTPUT).

If the external sensor is already activated (INP_H activated) when this function is executed, the system double-checks this position by moving backwards and forwards to always return to the home position from the same direction.

Programming

12.2 Index

The INDEX menu allows the definition of 50 different movements. To define each movement, the acceleration, maximum speed and the distance to be travelled must be programmed.

•										I	

FAULHABER

Note

For a fast deceleration in emergencyes (LL, LR, EE, EE1) a predefined deceleration can be set using the ED command, refer to the command set page 14.

The emergency exit function has high priority and is always executed immediately.

As long as EE is active no other function can be executed.

In a LL (Limit switch Left) or LR (Limit switch Right) emergency situation the corresponding opposite direction is only possible.

For all other functions, an already active function is always completed before the next one is executed.

If several functions are active at the same time, the one with the lowest input number is executed first (from top to bottom).

To run a program endlessly (activated via a INPUT, see example in INPUT 7 above) simply keep the selected input active.

The current program can be interrupted by the interrupt instruction IP.

By disactivating IP the interrupted program immediately continues.

Programming

12.4 Output function

We have seen that functions or instructions can be assigned to inputs. The outputs can also be similarly programmed, but with different possibilities.

🛃 Terr	ninal - MM_	WIN.TR	м				_ 0	×

13. Typical program example

Description of the application

For this example, using the MCBL 5004 we want to control the rotation of the Brushless DC-Servomotor type 3564 K 024 B. The speed and position are measured by the HEDS 5540 (2 channel, 500 lines with Z index) encoder.

The motor shaft should make 5 CW rotations (a total of 1'800°) in 5 seconds at a maximum speed of 61,5 rpm. Once the 5 rotations have been completed, the motor should stop for 2 seconds and then make 3 CCW rotations in 0.5 seconds at a maximum speed of 450 rpm. The second displacement is performed using both relative and absolute positioning. The home (starting) position is defined using the encoder Z index.

Input sequence

This particular sequence can be subdivided into four distinct phases:

Starting position	(home)
First displacement	(index 1)
Waiting time	_O WT
Second displacement S	(index 2)

How to enter the program data

It is important to remember that the motion controller works using the encoder line information. In other words, the displacement/movement, speed and acceleration parameters are entered in lines, lines/second and lines/second² respectively.

As already indicated, the motion controller's internal electronics multiply the encoder resolutions by 4.

The first step is to define the parameters of the various separate phases.

Definition of the home (starting) position

This instruction is given via the HOME FUNCTION menu

🛃 Terminal - MM_WIN.TRM	
<u>File Edit Settings Phone Transfers Help</u>	
HOME FUNCTION 1-> 5	and the second s
1 DIR_H 1=CW 2=CCW	° 0
2 SPE_H 50-10000	0
3 INP_H 1-8	0
4 DIR_Z 1=CW 2=CCW	1
5 SPE_Z 50-10000	500
CLR OUT 1=YES 0=NO	1 🚽

If, as in this case, the home function is executed using the encoder Z index, the first 3 lines are set at zero as above. In this example, the Z index is found by rotating the motor shaft CW at a speed of 125 lines/second. Once this position has been reached, all outputs are cleared.

Entering the first displacement parameters Go to the INDEX menu

🛃 Terminal -	MM_WIN.TR	м		_ 🗆 🗙
<u>File E</u> dit <u>S</u> et	tings <u>P</u> hone	<u>T</u> ransfers <u>H</u> elp	19. 19.	
INDEX	NR	1-50		1
ACCEL*	1000 50	10-5000 -500000	1 205	7
DIST TYPE	+-200 1=ABS	0000000 2=REL	1000	0 2
•				

FAULHABER

Total distance to be travelled

Equation: DIST [lines] = REV shaft [-] · 4 · CPR encoder [lines]

Therefore: DIST [lines] = $5 \cdot 4 \cdot 500 = 10000$ lines

The distance can also be measured using the encoder counter command, EC, in the execute function menu when the servo amplifier is unpowered (7-segment display at zero).

Speed				
Equation:	SPEED [lines/s] =	SPEED [rpm] 60	· 4 · CPR encoder [lines]	
Therefore:	SPEED [lines/s] =	61.5 rpm 60	· 4 · 500 lines = 2 050 lines/s	
Acceleration (= deceleration)			
Equation:	ACCEL[lines/s ²] =	SPEED [lines/s] T ACCEL [s]		
Therefore:	ACCEL[lines/s ²] =	2050 lines/s 0,122 s	= 16 803 lines/s² ≈ 17 000 lin	es/s ²

The acceleration (deceleration) time is calculated as follows:

Equation:	$T_{ACCEL}[s] = T_{TOT}[s] -$	DIST [lines]	TACCEL > 0
8	Source in the	SPEED [lines/s]	

Therefore:

TACCEL [s] = $5 \text{ s} - \frac{10\,000 \text{ lines}}{2050 \text{ lines/s}} = 0,122 \text{ s}$

FAULHABER

Note: The minimum acceleration accepted by the system is 10000 lines/s².

Entering the second displacement parameters

This is also programmed via the INDEX menu in the same way as the first displacement. From the last item on the INDEX menu we have the possibility of defining the two possible types of displacement (relative or absolute). The method for doing this is as described below:

Relative displacement

By relative we mean that the displacement commences from the position of the motor shaft at the time that the instruction is executed.

🛃 Terminal - I	MM_WIN.TBM			_ 🗆	×
<u>File E</u> dit <u>S</u> ett	ings <u>P</u> hone <u>T</u>	ransfers <u>H</u> elp	- 2007		
INDEX	NR	1-50		2	
ACCEL*	1000 1	10-5000		150	
SPEED	50-	-500000		15000	
DIST	+-2000	0000000		- 6000	
TYPE	1=ABS	2=REL		2	Ţ
- -				•	
	vO.				

Therefore to make three complete CCW rotations, the motor shaft is instructed to go back 6000 lines (negative) from its actual position.

Absolute displacement

Absolute displacement takes its reference point from the program's home position.

🛃 Terminal - I	MM_WIN.TBM	i de la companya de l	_ 0	X
<u>File E</u> dit <u>S</u> ett	tings <u>P</u> hone <u>T</u> ransl	fers <u>H</u> elp		
INDEX	NR	1-50	2	
ACCEL*	1000 10-	-5000	1500	
SPEED	50-50	0000	15000	
DIST	+-200000	00000	4000	
TYPE	1=ABS 2	2=REL	JO 1	-
•			<u> </u>	

FAULHABER

In this case to make three CCW rotations the instruction is given to go to the 4000 line position. In other words, to "return" to the 4 000 line position, the motor has to go back 6 000 lines from its actual position at 10 000 lines.

Waiting time

The 2 second waiting time is simply defined using the WAIT TIME instruction.

Writing the program

Now that all the phases have been defined, the final instructions are entered in the PROGRAM menu in the correct sequence. (See "input sequence" above).

### **Program example**

By going to the EXECUTE FUNCTION menu, the whole program (PG1) and the single lines can be tested in practice. For the above example, the lines are tested by entering HO to go to home, IX1 to execute the first displacement, IX2 for the second displacement. Entering PG1 executes the complete program.

#### Loop

There are two loop instructions, SET[letter] and JNZ[letter], which permit a particular program part to be repeated for a pre-defined number of times. Within any one program a maximum of five loops can be defined (from A to E).

In the following we instruct part of program PG1 (IX1, WT and IX2) to be repeated five times

### Call up program

#### 20. Call up program from binary coded digital inputs

When the application uses more than 8 digital inputs, the user should call them up via the binary coded digital inputs. In this case, the MODE in SET-UP VALUES menu should be set to 10 (or 12 or 13).

The input lines 9 - 12 are used as binary coded program numbers. The trigger to start the pre-selected program is input line 8. Program number 0 is not used. Therefore:

- pre-select program number with binary-switch (numbers 1-15)
- start program with start button S

### Call up program

#### 21. Example of sequential multi-axis application

The program number and program start of the sequential follow-on motion controllers are specified through the output of the lined up motion controller.

### **Advanced functions**

#### 22. Analogue input command

To activate the analogue input command function the MODE parameter in the SET UP VALUES menu must be set to 3 or 13 and the ANALOG FUNCT to:

**FAULHABER** 

- 0 for CW operation
- 1 for CCW operation
- 2 for CW and CCW operation

Attention: to start the system the home function (with all the parameters set to 0) must be execute first.

The maximum speed is defined with the SP command. For high dynamics we recommend increasing the AC value (AC > 2 000 000).

#### Potentiometer

		OPTIO
	PIN	Function
	• 1	GND
	• 2	10V
	3	PULSE / ch. B
	4	DIRECTION / ch. A

	6	PULSE* / ch. B*
	7	+/- 10V
	• 8	0 - 10V
	20	
	~	

### **Advanced functions**

#### 23. Stepper motor emulation

To activate the stepper motor emulation function the MODE parameter in the SET UP VALUES menu must be set to 2 or 12 and the INC PER PULSE according to the application requirements.

**SAME FAULHABER** 

			Sec.	1

	S. C.		NO.S	

#### 24. Second encoder - handwheel

Attention: function only available with optional hardware configuration.

To activate this function the SYNCH RATIO parameter in the SETUP VALUES must be set according to the application requirements. This parameter fixes the speed ratio between the second encoder and the first encoder mounted on the motor shaft.

### **Advanced functions**

#### 25. Second encoder - gearing and master - slave

The function is activated as for handwheel operation. In this case the second (master) encoder does not require a DC voltage supply

#### 26. RS485easy-Bus

With this feature up to 32 motion controllers can be adressed and controlled by one host computer using a simple RS485 interface. The connection principle is show below.

### Advanced functions

**FAULHABE** 

To simplify the connection Minimotor offers a special RS485 easy-Bus adapter and RJ45 cables.

#### Cable specification:

Modular RJ45 round shielded cable configuration 1:1. Twisted pairs 1&2, 3&6, 4&5, 7&8

#### Start-up Procedure

Attention: function only available with software version  $\ge$  3.00

 <u>Assign an adress</u> (number) to each motion controller (axis). This operation is made connecting the single motion controller to the RS232 interface and using the CI (card identifier) command.

Example: Cl 5 <CR> to assign the number 5 to a motion controller. The number can be checked using the command Cl ? <CR>

Attention: Each motion controller in the system must have a different number. Once the number is assigned it is memorized even if the power supply is switched off. The **CI** value goes from **0-99**. The number **0** is used as a default value for single axis application. For multi-axis operation a number from **1-99** should be used, Number **1** must always (see below).

- 2) <u>Realise an RS485 connections</u> and set the baud rate in the terminal emulator software to 19 200. To use the RS485 it is necessary to have a RS232/RS485 converter since PCs usually only offer a RS232 interface.
- 3) <u>To operate a motion controller</u> it is first necessary to adress it using the **RI** (request identifier) command.

Example: **RI 5 <CR>**. To make the prompt appear. If it does not appear check the RS485 connection and baud rate.

Using the **RI 0** command the host computer can control all the axis at the same time. In this case the echo from Motion Controller number **1** (in multi-axis the number **1** must always be used) will appear on the computer screen.

## Trouble-shooting

#### 27. Trouble-shooting

Error messages are shown on the 7-segment display as 2-digit alternating blinking numbers. There are two types of error code: one for input errors (WH wait high or WL wait low) and the other for controller errors (DP deviation position or over-heating).

**FAULHABER** 

Error code	Description	Remarks
01 to 12	Waiting for input (low or high)	<ul> <li>Continues if status has been reached or restart with HO, SM or PQ, PW.</li> </ul>
50 marsh	Deviation position too great	<ul> <li>Difference between the internal calculated position and actual motor position greater than the number of increments defined in DP (deviation position).</li> </ul>
60	Power stage over-heating	<ul> <li>&gt; 80° C detected by the temperature sensor.</li> </ul>
61	Power supply over voltage	<ul> <li>Power supply voltage or retarding energy on ballast circuit to high.</li> </ul>
62	Ballast circuit active too long	<ul> <li>If the ballast circuit is active for more than 5 seconds the power stage is switched off.</li> </ul>

#### 28. Operating system error

If the message "user program corrupted" appears on the screen, the operating system has to be turned off and re-started manually. This is done as follows:

remove the motion controller cover and set the S1 switch from OFF to ON

- re-load the MCxx_yyy.S19 program
- turn the S1 switch from ON to the OFF position and replace the cover

The system can now be switched on normally.

### Notice of use

#### 29. General usage instruction

#### Power supply and fuse

Any unstabilised DC power supply voltage within the motion controllers range:

CBL 5004	12 V ≤ Vm ≤ 50V
MCDC 5004	$12~V \leq Vm \leq 50V$

may be used, although it is advisable to keep this voltage as low as possible in order to minimize the EMI noise. Thus the optimum power supply voltage is given by the following equation:

**FAULHABER** 

	Vm [	$V] = 5V + R [\Omega] \cdot I_{max} [A] + k E [V/rpm] \cdot n_{max} [rpm]$	
Where:	R ke	= motor terminal resistance = motor back-EMF constant	
	Imax	= max. requested motor current for acceleration (= Іреак)	
	Nmax	= max. motor speed reach in the application Both motion controllers are provided with an internal fuse.	

#### **Braking energy**

When decelerating the motor, brake energy is developed. This energy increases the motion controller voltage supply. Therefore the motion controllers supplied with an internal ballast circuit which converts this energy into heat.

#### Wiring

A well known disadvantage of PWM (pulse width modulation), is that it generates a lot of interference. In order to reduce the effect of the interference there are some basic rules to follow:

- Use wires as short as possible
- Avoid running signal wires (logical and analog signal) in close proximity to power lead wires (power supply and motor power leads)
- Use shielded wires

### **Electro-magnetic compatibility**

#### 30. Electro-magnetic compatibility

EMC-approved shielding should be made according to the diagram below:

The motion controllers conform to the 89/336/CEE directive on electro-magnetic compatibility. For their evaluation, the following norms have been considered as far as applicable:

#### EN 50081-2 for emissions and EN 50082-2 for immunity

In order to respect these norms after installation in the application, the following must be observed:

- The installation instructions in the user's manuals must be respected.
- Connections must be made using shielded cables.
- All the components of the system must conform to the cited norms.
- Metal parts and shielding must be connected to common earth.
- The system must be supplied with a voltage corresponding to the specifications.
