HEIDENHAIN

Encoders for Servo Drives

This catalog is not intended as an overview of the HEIDENHAIN product program. Rather it presents a selection of **encoders for use on servo drives.**

In the **selection tables** you will find an overview of all HEIDENHAIN encoders for use on electric drives and the most important specifications. The descriptions of the **technical features** contain fundamental information on the use of rotary, angular, and linear encoders on electric drives.

The **mounting information** and the detailed **specifications** refer to the **rotary encoders** developed specifically for drive technology. Other rotary encoders are described in separate product catalogs.

For the **linear and angular encoders** listed in the selection tables, you will find detailed information such as mounting information, specifications and dimensions in the respective **product catalogs.**

Encoders for Servo Drives

Controlling systems for servo drives require measuring systems that provide feedback for the position and speed controllers and for electronic commutation.

The properties of encoders have decisive influence on important motor qualities such as:
- Positioning accuracy
- Speed stability
- Bandwidth, which determines drive command-signal response and disturbance rejection capability
- Power loss
- Size
- Quietness

Digital position and speed control

Rotary encoder (actual position value, actual speed value, commutation signal)
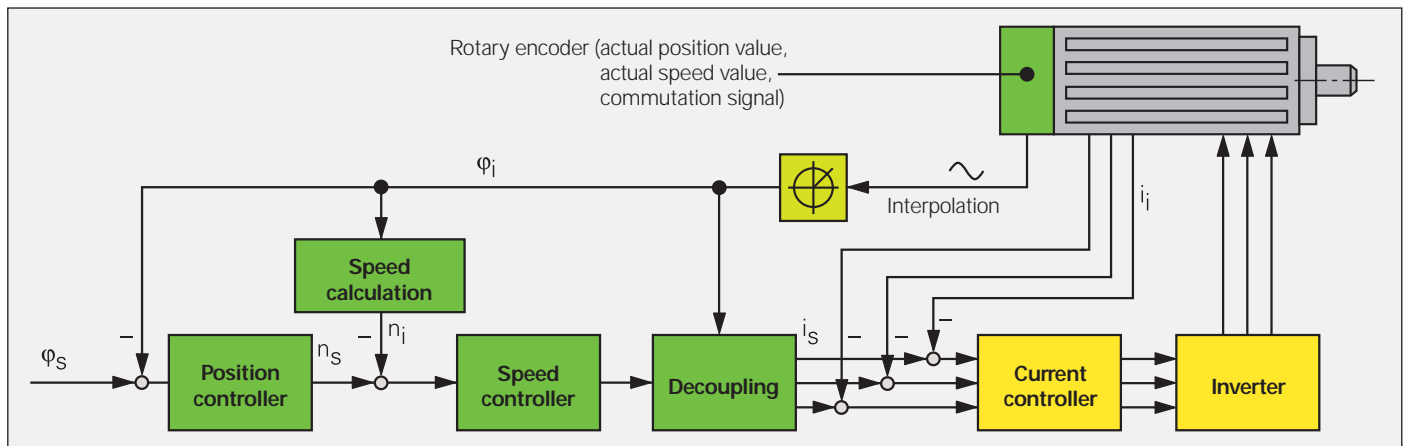

HEIDENHAIN offers the appropriate solution for any of a wide range of applications using both rotary and linear motors:

- Incremental rotary encoders with and without commutation tracks, absolute rotary encoders
- Incremental and absolute angle encoders
- Incremental and absolute linear encoders

Rotary encoders

All the HEIDENHAIN encoders shown in this catalog involve very little cost and effort for the motor manufacturer to mount and wire. Encoders for rotary motors are of short overall length. Some encoders, due to their special design, can perform functions otherwise handled by safety devices such as limit switches.

Motor for "digital" drive systems
(digital position and speed control)

Rotary encoder
Angle encoders

Linear encoders

Explanation of the Selection Tables

The tables on the following pages list the encoders suited for individual motor designs. The encoders are available with dimensions and output signals to fit specific types of motors (DC or AC).

Rotary encoders for mounting on motors

Rotary encoders for motors with forced ventilation are either built onto the motor housing or integrated. As a result, they are frequently exposed to the unfiltered forced-air stream of the motor and must have a high degree of protection, such as IP 64 or better. The permissible operating temperature seldom exceeds 100 °C.

In the selection table you will find
- Rotary encoders with mounted **stator couplings** with high natural frequency—virtually eliminating any limits on the bandwidth of the drive
- Rotary encoders for **separate shaft couplings,** which are particularly suited for **insulated mounting**
- Incremental rotary encoders with high quality **sinusoidal output signals** for digital speed control
- Absolute rotary encoders with purely digital data transfer or complementary sinusoidal incremental signals
- Incremental rotary encoders with **TTL- or HTL-compatible output signals**

For Selection Table see page 8
Rotary encoders for integration in motors

For motors without separate ventilation, the rotary encoder is built into the motor housing. This configuration places no stringent requirements on the encoder for a high degree of protection. The operating temperature within the motor housing, however, can reach 100 °C and higher.

In the selection table you will find
- Incremental rotary encoders for **operating temperatures** up to 120 °C, and absolute rotary encoders for operating temperatures up to 115 °C
- Rotary encoders with mounted **stator couplings** with high natural frequency—virtually eliminating any limits on the bandwidth of the drive
- Incremental rotary encoders for digital speed control with **sinusoidal output signals** of high quality—even at high operating temperatures
- Absolute rotary encoders **with purely digital data transfer** or complementary sinusoidal incremental signals
- Incremental rotary encoders with additional **commutation signal** for synchronous motors
- Incremental rotary encoders with **TTL-compatible output signals**

For Selection Table see page 10
Rotary encoders and angle encoders for integrated and hollow-shaft motors

Rotary encoders and angle encoders for these motors have **hollow through shafts** in order to allow supply lines, for example, to be conducted through the motor shaft—and therefore through the encoder. Depending on the conditions of the application, the encoders must either feature IP 66 protection or—for example with modular encoders using optical scanning—the machine must be designed to protect them from contamination.

In the selection table you will find
- Rotary encoders with the measuring standard on a steel drum for **shaft speeds up to 42 000 min^{-1}**
- Encoders with integral bearing, with stator coupling or modular design
- Encoders with high quality **absolute and/or incremental output signals**
- Encoders with **good acceleration performance** for a broad bandwidth in the control loop

For Selection Table see page 12
Linear encoders for linear motors

Linear encoders on linear motors supply the actual value both for the position controller and the velocity controller. They therefore form the basis for the servo characteristics of a linear drive. The linear encoders recommended for this application
- Have low position deviation during acceleration in the measuring direction
- Have high tolerance to acceleration and vibration in the lateral direction
- Are designed for high velocities
- Supply sinusoidal incremental signals of high quality

Exposed linear encoders are characterized by:
- Higher accuracy grades
- Higher traversing speeds
- Contact-free scanning, i.e., no friction between scanning head and scale

Exposed linear encoders are suited for applications in clean environments, for example on measuring machines or production equipment in the semiconductor industry.
For Selection Table see page 14

Sealed linear encoders are characterized by:
- A high degree of protection
- Simple installation

Sealed linear encoders are therefore ideal for applications in environments with airborne liquids and particles, such as on machine tools.
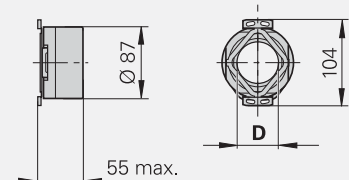

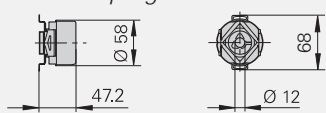

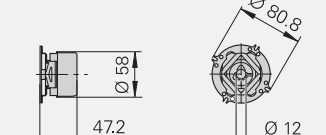

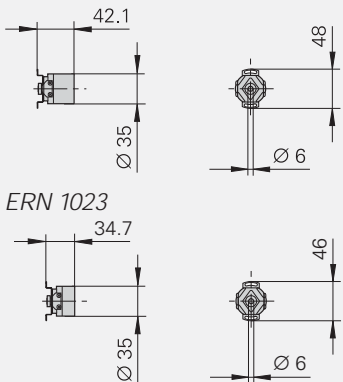

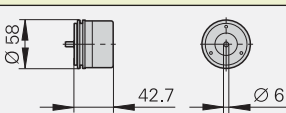

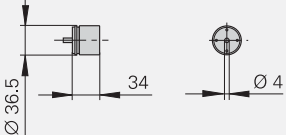

For Selection Table see page 16

General Information

Speed stability

To ensure **smooth drive performance**, an encoder must provide a **large number of measuring steps per revolution.** The encoders in the HEIDENHAIN product program are therefore designed to supply the necessary numbers of signal periods per revolution to meet the speed stability requirement.

HEIDENHAIN rotary and angular encoders featuring integral bearings and stator couplings provide very good performance: shaft misalignment within certain tolerances (see *Specifications*) do not cause any position error or impair speed stability.

At low speeds, the **position error of the encoder within one signal period** affects speed stability. In encoders with purely serial data transmission, the LSB (Least Significant Bit) goes into the speed stability. (See also *Measuring Accuracy.*)

Transmission of measuring signals

To ensure the best possible dynamic performance with digitally controlled motors, the sampling time of the speed controller should not exceed approx. 256 µs. The feedback values for the position and speed controller must therefore be available in the controlling system with the least possible delay.

High clock frequencies are needed to fulfill such demanding time requirements on position values transfer from the encoder to the controlling system with a serial data transmission (see also *Interfaces; Absolute Position Values*). HEIDENHAIN encoders for electric drives therefore provide the position values via the fast, purely serial EnDat 2.2 interface, or transmit additional **incremental signals,** which are available immediately for use in the subsequent electronics for speed and position control.

For **standard drives,** manufacturers primarily use HEIDENHAIN absolute encoders without integral bearing (ECI/EQI) or rotary encoders with **TTL** or **HTL compatible output signals**—as well as additional commutation signals for permanent-magnet DC drives.

For **digital speed control** on machines with **high requirements for dynamics,** a large number of measuring steps is required—usually above 500 000 per revolution.
For applications with standard drives, as with resolvers, approx. 60 000 measuring steps per revolution are sufficient.

HEIDENHAIN encoders for drives with digital position and speed control therefore provide **sinusoidal incremental signals with signal levels of 1 V$_{PP}$** which, thanks to their high quality, can be highly interpolated in the subsequent electronics (Diagram 1). For example, a rotary encoder with 2 048 signal periods per revolution and a 1 024-fold or 4 096-fold subdivision in the subsequent electronics produces approx. **2 or 8 million measuring steps per revolution, respectively.** This corresponds to a resolution of 21 (23) bits. Even at shaft speeds of 12 000 min^{-1}, the signal arrives at the input circuit of the controlling system with a frequency of only approx. 400 kHz (Diagram 2). 1-V$_{PP}$ incremental signals permit cable lengths up to 150 meters. (See also *Incremental Signals – 1 V$_{PP}$*)

Diagram 1:
Signal periods per revolution and the resulting number of measuring steps per revolution as a function of the subdivision factor
HEIDENHAIN absolute encoders for "digital" drives also supply additional sinusoidal incremental signals with the same characteristics as those described above. Absolute encoders from HEIDENHAIN use the EnDat interface (for **En**coder **Dat**a) for the **serial data transmission** of absolute position values and other information for **automatic self-configuration, monitoring and diagnosis.** (See *Absolute Position Values – EnDat.*) This makes it possible to use the same subsequent electronics and cabling technology for all HEIDENHAIN encoders.

Important encoder specifications can be read from the memory of the EnDat encoder for automatic self-configuration, and motor-specific parameters can be saved in the OEM memory area of the encoder. The usable size of the OEM memory on the rotary encoders in the current catalogs is at least 1.4 KB ($\triangleq$ 704 EnDat words); for the ATEX encoders it is 0.44 KB ($\triangleq$ 224 EnDat words).

Most absolute encoders themselves already subdivide the sinusoidal scanning signals by a factor of 4 096 or greater. If the transmission of absolute positions is fast enough (for example, EnDat 2.1 with 2 MHz or EnDat 2.2 with 8 MHz clock frequency), these systems can do without incremental signal evaluation.

Benefits of this data transmission technology include greater noise immunity of the transmission path and less expensive connectors and cables. Encoders with EnDat2.2 interface offer the additional feature of being able to evaluate an external temperature sensor, located in the motor coil, for example. The digitized temperature values are transmitted as part of the EnDat 2.2 protocol without an additional line.

Bandwidth
The attainable gain for the position and speed control loops, and therefore the bandwidth of the drives for command response and control reliability, are sometimes limited by the rigidity of the coupling between the motor shaft and encoder shaft as well as by the natural frequency of the coupling. HEIDENHAIN therefore offers rotary and angular encoders for high-rigidity shaft coupling. The stator couplings mounted on the encoders have a **high natural frequency** up to 2 kHz. For the inductive rotary encoders, the stator and rotor are firmly screwed to the motor housing and to the shaft. This means that the rigidity of the motor shaft is of the most significance for the attainable natural frequency. (See also *Mechanical Design and Installation.*)

Size
A higher permissible operating temperature permits a smaller motor size for a specific rated torque. Since the temperature of the motor also affects the temperature of the encoder, HEIDENHAIN offers encoders for **permissible operating temperatures up to 120 °C.** These encoders make it possible to design machines with smaller motors.

Power loss and quietness
The power loss of the motor, the accompanying heat generation, and the acoustic noise during operation are influenced by the position error of the encoder within one signal period. For this reason, rotary encoders with a high signal quality of better than $\pm$ 1 % of the signal period are preferred. (See also *Measuring Accuracy.*)

Diagram 2:
Shaft speed and resulting output frequency as a function of the number of signal periods per revolution
Linear Encoders for Linear Drives
General Information

Selection criteria for linear encoders

HEIDENHAIN recommends the use of **exposed linear encoders** whenever the severity of contamination inherent in a particular machine environment does not preclude the use of optical measuring systems, and if relatively high accuracy is desired, e.g. for high-precision machine tools and measuring equipment, or for production, testing and inspecting equipment in the semiconductor industry.

Particularly for applications on machine tools that release coolants and lubricants, HEIDENHAIN recommends **sealed linear encoders.** Here the requirements on the mounting surface and on machine guideway accuracy are less stringent than for exposed linear encoders, and therefore installation is faster.

Speed stability

To ensure smooth-running servo performance, the linear encoder must permit a resolution commensurate with the given speed control range:
- On handling equipment, resolutions in the range of several microns are sufficient.
- Feed drives for machine tools need resolutions of 0.1 μm and finer.
- Production equipment in the semiconductor industry requires resolutions of a few nanometers.

At low traversing speeds, the **position error within one signal period** has a decisive influence on the speed stability of linear motors. (See also *Measuring Accuracy.*)

Traversing speeds

Exposed linear encoders function without contact between the scanning head and the scale. The maximum permissible traversing speed is limited only by the cutoff frequency (–3 dB) of the output signals.

On sealed linear encoders, the scanning unit is guided along the scale on a ball bearing. Sealing lips protect the scale and scanning unit from contamination. The ball bearing and sealing lips permit mechanical traversing speeds up to **180 m/min**.

Signal period and resulting measuring step as a function of the subdivision factor
Transmission of measuring signals

The information above on rotary and angle encoder signal transmission essentially applies also to linear encoders. If, for example, one wishes to traverse at a minimum velocity of 0.01 m/min with a sampling time of 250 µs, and if one assumes that the measuring step should change by at least one measuring step per sampling cycle, then one needs a measuring step of approx. 0.04 µm. To avoid the need for special measures in the subsequent electronics, input frequencies should be limited to less than 1 MHz.

Linear encoders with sinusoidal output signals are therefore best suited for high traversing speeds and small measuring steps. Sinusoidal voltage signals with levels of **1 V$_{PP}$** attain a –3 dB cutoff frequency of approx. 200 kHz and more at a permissible cable length of up to 150 m.

The figure below illustrates the relationship between output frequency, traversing speeds, and signal periods of linear encoders. Even at a signal period of 4 µm and a traversing velocity of 70 m/min, the frequency reaches only 300 kHz.

Bandwidth

On linear motors, a coupling lacking in rigidity can limit the bandwidth of the position control loop. The manner in which the linear encoder is mounted on the machine has a very significant influence on the rigidity of the coupling. (See *Design Types and Mounting*.)

On sealed linear encoders, the scanning unit is guided along the scale. A coupling connects the scanning carriage with the mounting block and compensates the misalignment between the scale and the machine guideways. This permits relatively large mounting tolerances. The coupling is very rigid in the measuring direction and is flexible in the perpendicular direction. If the coupling is insufficiently rigid in the measuring direction, it could cause low natural frequencies in the position and velocity control loops and limit the bandwidth of the drive.

The sealed linear encoders recommended by HEIDENHAIN for linear motors generally have a **natural frequency of coupling greater than 650 Hz or 2 kHz** in the measuring direction, which in most applications exceeds the mechanical natural frequency of the machine and the bandwidth of the velocity control loop by factors of at least 5 to 10. HEIDENHAIN linear encoders for linear motors therefore have practically no limiting effect on the position and speed control loops.

Traversing speed and resulting output frequency as a function of the signal period
Safety-Related Position Measuring Systems

With the designation Functional Safety, HEIDENHAIN offers safety-related position measuring systems that are based on pure serial data transfer via EnDat 2.2 and can be used in safety-oriented applications. A safety-related position measuring system can be used as a single-encoder system in conjunction with a safe control in applications with control category SIL-2 (according to EN 61508/EN 61800-5-2) or performance level "d" (according to EN ISO 13849). Reliable transmission of the position is based on two independently generated absolute position values and on error bits. These are then provided to the safe control.

Basic principle

HEIDENHAIN measuring systems for safety-oriented applications are tested for compliance with EN ISO 13849-1 (successor to EN 954-1) as well as EN 61508 and EN 61800-5-2. These standards describe the assessment of safety-oriented systems, for example based on the failure probabilities of integrated components and subsystems.

This modular approach helps manufacturers of safety-oriented systems to implement their complete systems, because they can begin with subsystems that have already been qualified. Safety-related position measuring systems with purely serial data transmission via EnDat 2.2 accommodate this technique.

In a safe drive, the safety-related position measuring system is such a subsystem.

A **safety-related position measuring system** consists of:

- Encoder with EnDat 2.2 transmission component
- Data transmission line with EnDat 2.2 communication and HEIDENHAIN cable
- EnDat 2.2 receiver component with monitoring function (EnDat master)

In practice, the **complete "safe servo drive" system** consists of:

- Safety-related position measuring system
- Safety-oriented control (including EnDat master with monitoring functions)
- Power stage with motor power cable and drive
- Physical connection between encoder and drive (e.g. shaft connection/coupling)

Field of application

Safety-related position measuring systems from HEIDENHAIN are designed so that they can be used as single-encoder systems in applications with control category SIL-2 (according to EN 61508). This corresponds to performance level "d" of EN ISO 13849 or category 3 (according to EN 954-1). Also, the functions of the safety-related position measuring system can be used for the safety functions in the complete system (also see EN 61800-5-2) as listed in the table below:

SS1	Safe Stop 1	Safe Stop 1
SS2	Safe Stop 2	Safe Stop 2
SOS	Safe Operating Stop	Safe Operating Stop
SLA	Safely Limited Acceleration	Safely Limited Acceleration
SAR	Safe Acceleration Range	Safe Acceleration Range
SLS	Safely Limited Speed	Safely Limited Speed
SSR	Safe Speed Range	Safe Speed Range
SLP	Safely Limited Position	Safely Limited Position
SLI	Safely Limited Increment	Safely Limited Increment
SDI	Safe Direction	Safe Direction
SSM	Safe Speed Monitor	Safe report of the limited speed

Safety functions according to EN 61800-5-2
Complete safe drive system

Function

The safety strategy of the position measuring system is based on two mutually independent position values and additional error bits produced in the encoder and transmitted over the EnDat 2.2 protocol to the EnDat master. The EnDat master assumes various monitoring functions with which errors in the encoder and during transmission can be revealed. The two position values are then compared. The EnDat master then makes the data available to the safe control. The control periodically tests the safety-related position measuring system to monitor its correct operation.

The architecture of the EnDat 2.2 protocol makes it possible to process all safety-relevant information and control mechanisms during unconstrained controller operation. This is possible because the safety-relevant information is saved in the additional information. According to EN 61508, the architecture of the position measuring system is regarded as a single-channel tested system.

Documentation on the integration of the position measuring system

The intended use of position measuring systems places demands on the control, the machine designer, the installation technician, service, etc. The necessary information is provided in the documentation for the position measuring systems.

In order to be able to implement a position measuring system in a safety-oriented application, a suitable control is required. The control assumes the fundamental task of communicating with the encoder and safely evaluating the encoder data.

The requirements for integrating the EnDat master with monitoring functions in the safe control are described in the document **"Specification of the E/E/PES safety requirements for the EnDat master and measures for safe control" (document 533095)**. It contains, for example, specifications on the evaluation and processing of position values and error bits, and on electrical connection and cyclic tests of position measuring systems.

Machine and plant manufacturers need not attend to these details. These functions must be provided by the control. Product information sheets, catalogs and mounting instructions provide information to aid the selection of a suitable encoder. The **product information sheets** and **catalogs** contain general data on function and application of the encoders as well as specifications and permissible ambient conditions. The **mounting instructions** provide detailed information on installing the encoders.

The architecture of the safety system and the diagnostic possibilities of the control may call for further requirements. For example, the operating instructions of the control must explicitly state whether fault exclusion is required for the loosening of the mechanical connection between the encoder and the drive. The machine designer is obliged to inform the installation technician and service technicians, for example, of the resulting requirements (see also information under "Safety-Related Characteristic Values").

Safety-related position measuring system
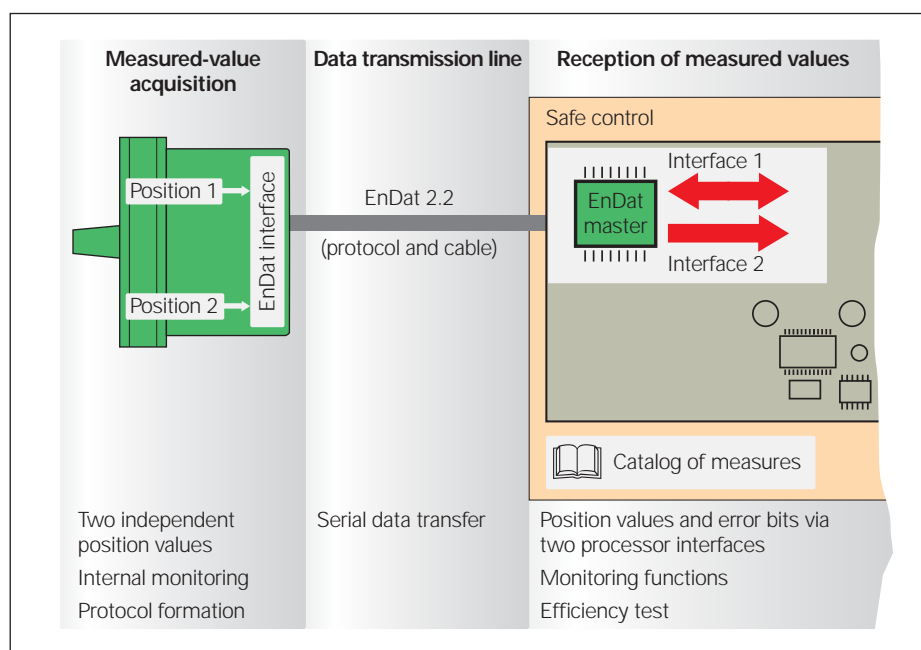

For more information on the topic of Functional Safety, refer to the Technical Information documents *Safety-Related Position Measuring Systems* and *Safety-Related Control Technology* as well as the Product Information document of the Functional Safety encoders.

Measuring Principles
Measuring Standard

HEIDENHAIN encoders with optical scanning incorporate measuring standards of periodic structures known as graduations.
These graduations are applied to a carrier substrate of glass or steel. The scale substrate for large diameters is a steel tape.

HEIDENHAIN manufactures the precision graduations in specially developed, photolithographic processes.
- AURODUR: Matte-etched lines on gold-plated steel tape with grating periods of typically 40 µm
- METALLUR: Contamination-tolerant graduation of metal lines on gold, with typical graduation period of 20 µm
- DIADUR: Extremely robust chromium lines on glass (typical graduation period 20 µm) or three-dimensional chrome structures (typical graduation period of 8 µm) on glass
- SUPRADUR phase grating: optically three dimensional, planar structure; particularly tolerant to contamination; typical graduation period of 8 µm and less
- OPTODUR phase grating: optically three dimensional, planar structure with particularly high reflectance, typical graduation period of 2 µm and less.

Magnetic encoders use a graduation carrier of magnetizable steel alloy. A graduation consisting of north poles and south poles is formed with a grating period of 400 µm. Due to the short distance of effect of electromagnetic interaction, and the very narrow scanning gaps required, finer magnetic graduations are not practical.

Encoders using the inductive scanning principle have graduation structures of copper. The graduation is applied to a carrier material for printed circuits.

With the **absolute measuring method,** the position value is available from the encoder immediately upon switch-on and can be called at any time by the subsequent electronics. There is no need to move the axes to find the reference position. The absolute position information is read from the **grating on the circular scale,** which is designed as a serial code structure or consists of several parallel graduation tracks.

A separate incremental track or the track with the finest grating period is interpolated for the position value and at the same time is used to generate an optional incremental signal.

In **singleturn encoders,** the absolute position information repeats itself with every revolution. **Multiturn encoders** can also distinguish between revolutions.
Circular graduations of absolute rotary encoders

With the **incremental measuring method**, the graduation consists of a periodic grating structure. The position information is obtained **by counting** the individual increments (measuring steps) from some point of origin. Since an absolute reference is required to ascertain positions, the graduated disks are provided with an additional track that bears a **reference mark**.

The absolute position established by the reference mark is gated with exactly one measuring step.

The reference mark must therefore be scanned to establish an absolute reference or to find the last selected datum.
Circular graduations of incremental rotary encoders

Scanning Methods

Photoelectric scanning

Most HEIDENHAIN encoders operate using the principle of photoelectric scanning. Photoelectric scanning of a measuring standard is contact-free, and as such, free of wear. This method detects even very fine lines, no more than a few microns wide, and generates output signals with very small signal periods.

The ERN, ECN, EQN, ERO and ROD, RCN, RQN rotary encoders use the imaging scanning principle.

Put simply, the imaging scanning principle functions by means of projected-light signal generation: two graduations with equal or similar grating periods are moved relative to each other—the scale and the scanning reticle. The carrier material of the scanning reticle is transparent, whereas the graduation on the measuring standard may be applied to a transparent or reflective surface.

When parallel light passes through a grating, light and dark surfaces are projected at a certain distance. An index grating with the same or similar grating period is located here. When the two gratings move in relation to each other, the incident light is modulated: if the gaps are aligned, light passes through. If the lines of one grating coincide with the gaps of the other, no light passes through. Photovoltaic cells or a structured photosensor convert these variations in light intensity into nearly sinusoidal electrical signals. Practical mounting tolerances for encoders with the imaging scanning principle are achieved with grating periods of 10 µm and larger.

The ECN 1325 and EQN 1337 absolute rotary encoders with optimized scanning have a single large photosensor instead of a group of individual photoelements. Its structures have the same width as that of the measuring standard. This makes it possible to do without the scanning reticle with matching structure.
Photoelectric scanning according to the imaging scanning principle

Other scanning principles

Some encoders function according to other scanning methods. ERM encoders use a permanently magnetized MAGNODUR graduation that is scanned with magnetoresistive sensors.

ECI/EQI/EBI rotary encoders operate according to the inductive measuring principle. Here, moving graduation structures modulate a high-frequency signal in its amplitude and phase. The position value is always formed by sampling the signals of all receiver coils distributed evenly around the circumference.

Electronic Commutation with Position Encoders

Commutation in permanent-magnet three-phase motors

Before start-up, permanent-magnet three-phase motors must have an absolute position value available for electrical commutation. HEIDENHAIN rotary encoders are available with different types of rotor position recognition:

- **Absolute rotary encoders** in singleturn and multiturn versions provide the absolute position information immediately after switch-on. This makes it immediately possible to derive the exact position of the rotor and use it for electronic commutation.

- **Incremental rotary encoders with** a second track—the **Z1 track**—provide one sine and one cosine signal (C and D) for each motor shaft revolution in addition to the incremental signals. For sine commutation, rotary encoders with a Z1 track need only a subdivision unit and a signal multiplexer to provide both the absolute rotor position from the Z1 track with an accuracy of ± 5° and the position information for speed and position control from the incremental track (see also *Interfaces—Commutation signals*).

- **Incremental rotary encoders with block commutation tracks** also output three commutation signals U, V and W. which are used to drive the power electronics directly. These encoders are available with various commutation tracks. Typical versions provide 3 signal periods (120° mech.) or 4 signal periods (90° mech.) per commutation and revolution. Independently of these signals, the incremental square-wave signals serve for position and speed control. (See also *Interfaces—Commutation signals*.)

Commutation of synchronous linear motors

Like absolute rotary and angular encoders, absolute linear encoders of the LC series provide the exact position of the moving motor part immediately after switch-on. This makes it possible to start with maximum holding load on vertical axes even at a standstill.

Circular scale with serial code track and incremental track

Circular scale with Z1 track
Circular scale with block commutation tracks

Keep in mind the switch-on behavior of the encoders (see *General Electrical Information*).

Measuring Accuracy

The quantities influencing the accuracy of **linear encoders** are listed in the *Linear Encoders for Numerically Controlled Machine Tools* and *Exposed Linear Encoders* catalogs.

The **accuracy of angular measurement** is mainly determined by:
1. Quality of the graduation
2. Scanning quality
3. Quality of the signal processing electronics
4. Eccentricity of the graduation to the bearing
5. Error due to radial deviation of the bearing
6. Elasticity of the encoder shaft and coupling with the drive shaft
7. Elasticity of the stator coupling (ERN, ECN, EQN) or shaft coupling (ROD, ROC, ROQ)

In positioning tasks, the accuracy of the angular measurement determines the accuracy of the positioning of a rotary axis. The **system accuracy** given in the Specifications applies to a temperature of 20 °C, and is defined as follows:
The extreme values of the total error of a position—with respect to the mean value—are within the system accuracy ± a.
• For rotary encoders with integral bearing and integrated stator coupling, this value also includes the deviation due to the shaft coupling.

• For rotary encoders with integral bearing and separate shaft coupling, the angle error of the coupling must be added.
• For rotary encoders without integral bearing, deviations resulting from mounting, from the bearing of the drive shaft, and from adjustment of the scanning head must be expected in addition to the system error (see next page).

The system accuracy reflects position errors within one revolution as well as those within one signal period.

Position error within one revolution becomes apparent in larger angular motions.

Position deviations within one signal period already become apparent in very small angular motions and in repeated measurements. They especially lead to speed ripples in the rotational-speed control loop. HEIDENHAIN rotary encoders with integral bearing permit interpolation of the sinusoidal output signal with subdivision accuracies of better than ± 1 % of the signal period.

Example
Rotary encoder with 2048 sinusoidal signal periods per revolution:
One signal period corresponds to approx. 600".
This results in maximum position deviations within one signal period of approx. ± 6".

The position error of the encoder within one signal period always affects the calculation of the actual speed on the basis of the actual position values of two successive sampling cycles. The position error of the encoder within one revolution is relevant for the speed control loop only if no more than a few actual position values per revolution are being evaluated. For example: a sampling time of 250 µs and a speed of n ≈ 24000 min^{-1} result in only 10 samples per revolution.

Temperatures as high as 120 C, which can typically be found in motors, cause only a very small position error in HEIDENHAIN encoders.

Encoders with square-wave output signals have a position error of approx. ± 3 % of the signal period. These signals are suitable for up to 100-fold phase-locked loop subdivision.

Position error within one signal period

Position errors within one revolution

Position error within one signal period
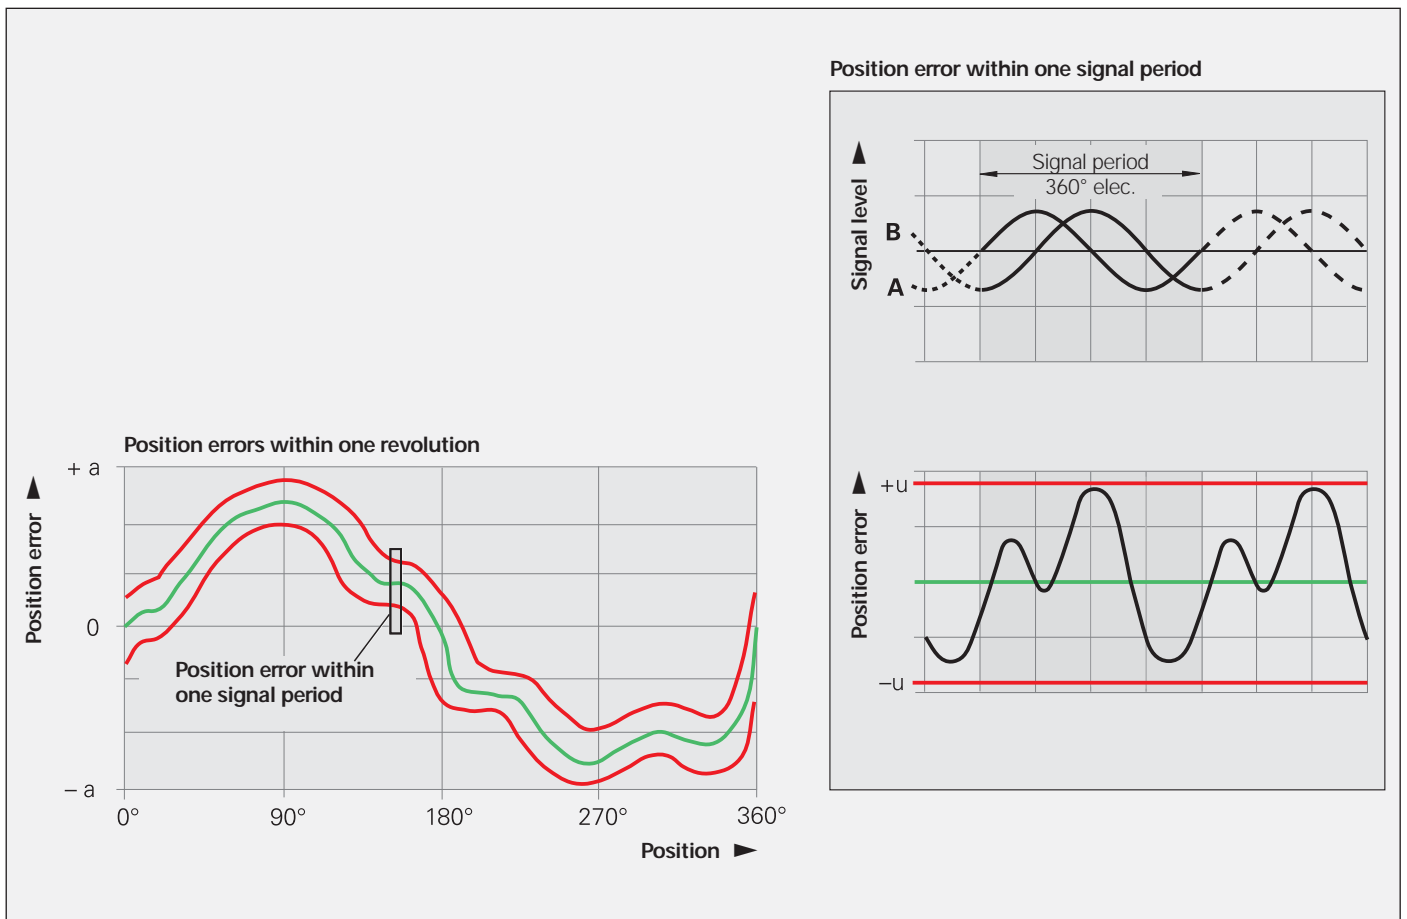

Measuring Accuracy
Rotary Encoders without Integral Bearing

Rotary Encoders with Photoelectric Scanning

In addition to the system accuracy, the mounting and adjustment of the scanning head normally have a significant effect on the accuracy that can be achieved by rotary encoders without integral bearings with photoelectric scanning. Of particular importance are the mounting eccentricity and radial runout of the measured shaft.

Example

ERO 1420 rotary encoder with a mean graduation diameter of 24.85 mm:
A radial runout of the measured shaft of 0.02 mm results in a position error within one revolution of ± 330 angular seconds.

To evaluate the **accuracy of modular rotary encoders without integral bearing** (ERO), each of the significant errors must be considered individually.

1. Directional deviations of the graduation

ERO: The extreme values of the directional deviation with respect to their mean value are shown in the *Specifications* as the graduation accuracy for each model. The graduation accuracy and the position error within a signal period comprise the system accuracy.

2. Errors due to eccentricity of the graduation to the bearing

Under normal circumstances, the bearing will have a certain amount of radial deviation or geometric error after the disk/hub assembly is mounted. When centering using the centering collar of the hub, please note that, for the encoders listed in this catalog, HEIDENHAIN guarantees an eccentricity of the graduation to the centering collar of under 5 µm. For the modular rotary encoders, this accuracy value presupposes a diameter deviation of zero between the drive shaft and the "master shaft."

If the centering collar is centered on the bearing, then in a worst-case situation both eccentricity vectors could be added together.

Resultant measured deviations Δφ for various eccentricity values e as a function of mean graduation diameter D
The following relationship exists between the eccentricity e, the mean graduation diameter D and the measuring error $\Delta\varphi$ (see illustration below):

$$\Delta\varphi = \pm\, 412 \cdot \frac{e}{D}$$

$\Delta\varphi$ = Measuring error in " (angular seconds)
e = Eccentricity of the radial grating to the bearing in µm
D = Mean graduation diameter in mm

Model	Mean graduation diameter D	Error per 1 µm of eccentricity
ERO 1420 **ERO 1470** **ERO 1480**	D = 24.85 mm	± 16.5"
ERO 1225 **ERO 1285**	D = 38.5 mm	± 10.7"

3. Error due to radial deviation of the bearing

The equation for the measuring error $\Delta\varphi$ is also valid for radial deviation of the bearing if the value e is replaced with the eccentricity value, i.e. half of the radial deviation (half of the displayed value).
Bearing compliance to radial shaft loading causes similar errors.

4. Position error within one signal period $\Delta\varphi_u$

The scanning units of all HEIDENHAIN encoders are adjusted so that without any further electrical adjustment being necessary while mounting, the maximum position error values within one signal period will not exceed the values listed below.

Model	Line count	Position error within one signal period $\Delta\varphi_u$	
		TTL	1 V$_{PP}$
ERO	2048	≤ ± 19.0"	≤ ± 6.5"
	1500	≤ ± 26.0"	≤ ± 8.7"
	1024	≤ ± 38.0"	≤ ± 13.0"
	1000	≤ ± 40.0"	≤ ± 14.0"
	512	≤ ± 76.0"	≤ ± 25.0"

The values for the position errors within one signal period are already included in the system accuracy. Larger errors can occur if the mounting tolerances are exceeded.

Rotary Encoders with Inductive Scanning

For rotary encoders without integrated bearing with inductive scanning, the attainable accuracy depends on the power supply, the temperature, the rotational speed, the working gap between the rotor and stator, and on the mounting conditions. Further information is available upon request.

Mechanical Design Types and Mounting
Rotary Encoders with Integral Bearing and Stator Coupling

ECN/EQN/ERN rotary encoders have integrated bearings and a mounted stator coupling. The encoder shaft is directly connected with the shaft to be measured. During angular acceleration of the shaft, the stator coupling must absorb only that torque caused by friction in the bearing. ECN/EQN/ERN rotary encoders therefore provide excellent dynamic performance and a high natural frequency.

Benefits of the stator coupling:
- No axial mounting tolerances between shaft and stator housing for ExN 1300 and ExN 1100
- High natural frequency of the coupling
- High torsional rigidity of shaft coupling
- Low mounting or installation space requirement
- Simple installation

Mounting the ECN/EQN/ERN 1100 and ECN/EQN/ERN 1300
The blind hollow shaft or the taper shaft of the encoder is connected at its end through a central screw with the measured shaft. The encoder is centered on the motor shaft by the hollow shaft or taper shaft. The stator of the encoder is clamped in a location hole by an axially tightened screw.

Mounting the ECN/EQN/ERN 1000 and ERN 1x23
The rotary encoder is slid by its hollow shaft onto the measured shaft and fastened by two screws or three eccentric clamps. The stator is mounted without a centering flange to a flat surface with four cap screws or with 2 cap screws and special washers.

Mechanical Design Types and Mounting
Rotary Encoders without Integral Bearing

The **ERO, ECI/EQI** rotary encoders without integral bearing consist of a scanning head and a graduated disk, which must be adjusted to each other very exactly. A precise adjustment is an important factor for the attainable measuring accuracy.

The **ERO** modular rotary encoders consist of a graduated disk with hub and a scanning unit. They are particularly well suited for applications with limited installation space and negligible axial and radial runout, or for applications where friction of any type must be avoided.

In the **ERO 1200** series, the disk/hub assembly is slid onto the shaft and adjusted to the scanning unit. The scanning unit is aligned on a centering collar and fastened on the mounting surface.

The **ERO 1400** series consists of miniature modular encoders. These rotary encoders have a special built-in **mounting aid** that centers the graduated disk to the scanning unit and adjusts the gap between the disk and the scanning reticle. This makes it possible to install the encoder in a very short time. The encoder is supplied with a cover cap for protection from extraneous light.

ERO 1400

Mounting the **ERO**

Mounting accessories for **ERO 1400**

Mounting the **ECI 119**

The **ECI/EQI 1100** inductive rotary encoders are mounted in axial direction. The blind hollow shaft is attached with a central screw. The stator of the encoder is clamped against a shoulder by two axial screws.

The scanning gap between the rotor and stator is predetermined by the mounting situation. Retroactive adjustment is not possible.

The maximum permitted deviation indicated in the mating dimensions applies to mounting as well as to operation. Tolerances used during mounting are therefore not available for axial motion of the shaft during operation.

Once the encoder has been mounted, the actual working gap between the rotor and stator can be measured indirectly via the signal amplitude in the rotary encoder, using the adjusting and testing package. The characteristic curves show the correlation between the signal amplitude and the deviation from the ideal scanning gap, depending on various ambient conditions.

The example of ECI/EQI 1100 shows the resulting deviation from the ideal scanning gap for a signal amplitude of 80% at ideal conditions. Due to tolerances within the rotary encoder, the deviation is between +0.07 mm and +0.15 mm. This means that the maximum permissible motion of the drive shaft during operation is between –0.27 mm and +0.05 mm (green arrows).
Mounting the **ECI/EQI 1100**
ECI/EQI 1100 with EnDat 2.1
ECI 1118 with EnDat 2.2

Accessories for ECI 119, ECI/EQI 1100
For testing the scanning gap

Encoder cable
For IK 215, PWM 20, inc. 3 adapter connectors, 12-pin and 3 adapter connectors, 15-pin
ID 621 742-01

Software (for Windows 2000/XP)
For inspecting the output signals in combination with the adjusting and testing package (see *HEIDENHAIN Measuring and Testing Devices*)
ID 539 862-xx

15-pin adapter connector
Three units
ID 528 694-02
Mounting accessories for **ECI/EQI**

The **ECI/EQI 1300** inductive rotary encoders are mechanically compatible with the ExN 1300 photoelectric encoders. The taper shaft (a bottomed hollow shaft is available as an alternative) is fastened with a central screw. The stator of the encoder is clamped by an axially tightened screw in the location hole. The scanning gap between rotor and stator must be set during mounting.
Mounting the **ECI/EQI 1300**

Accessories for adjusting the ECI/EQI 1300
To adjust the encoder, you will need:

Adjustment aid for setting the gap
ID 335 529-xx

Mounting aid for adjusting the rotor position to the motor emf
ID 352 481-xx

Encoder cable
For IK 215, PWM 20, inc. 3 adapter connectors, 12-pin and 3 adapter connectors, 15-pin

Aligning the Rotary Encoders to the Motor EMF

Synchronous motors require information on the rotor position immediately after switch-on. This information can be provided by rotary encoders with additional commutation signals, which provide relatively rough position information. Also suitable are absolute rotary encoders in multiturn and singleturn versions, which transmit the exact position information within a few angular seconds (see also *Electronic Commutation with Position Encoders*). When these encoders are mounted, the rotor positions of the encoder must be assigned to those of the motor in order to ensure the most constant possible motor current. Inadequate assignment to the motor emf will cause loud motor noises and high power loss.

Rotary encoders with integral bearing
First, the rotor of the motor is brought to a preferred position by the application of a DC current. **Rotary encoders with commutation signals** are aligned approximately—for example with the aid of the line markers on the encoder or the reference mark signal—and mounted on the motor shaft. The fine adjustment is quite easy with a PWM 9 phase angle measuring device (see *HEIDENHAIN Measuring and Testing Devices*): the stator of the encoder is turned until the PWM 9 displays, for example, the value zero as the distance from the reference mark.
Absolute rotary encoders are at first mounted as a complete unit. Then the preferred position of the motor is assigned the value zero. The adjusting and testing package (see *HEIDENHAIN Measuring and Testing Devices*) serve this purpose. They feature the complete range of EnDat functions and make it possible to shift datums, set write protection against unintentional changes in saved values, and use further inspection functions.

Rotary encoders without integral bearing
ECI/EQI rotary encoders are mounted as complete units and then adjusted with the aid of the adjusting and testing package. For the ECI/EQI with pure serial operation, electronic compensation is also possible: the ascertained compensation value can be saved in the encoder and read out by the control electronics to calculate the position value. ECI/EQI 1300 also permit manual alignment. The central screw is loosened again and the encoder rotor is turned with the mounting aid to the desired position until, for example, an absolute value of approximately zero appears in the position data.
Motor current of adjusted and very poorly adjusted rotary encoder
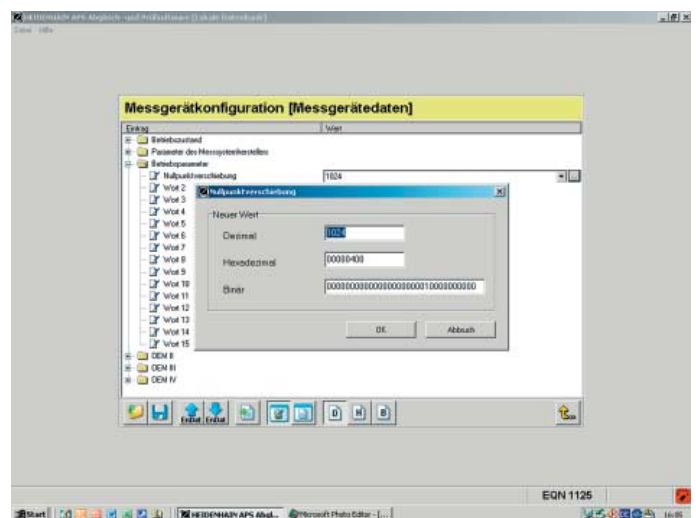

Aligning the rotary encoder to the motor emf with the aid of the adjusting and testing software

General Mechanical Information

UL certification
All rotary encoders and cables in this brochure comply with the UL safety regulations for the USA and the "CSA" safety regulations for Canada.

Acceleration
Encoders are subject to various types of acceleration during operation and mounting.

- **Vibration**
  The encoders are qualified on a test stand to operate with the specified acceleration values from 55 to 2000 Hz in accordance with EN 60068-2-6. However, if the application or poor mounting cause long-lasting resonant vibration, it can limit performance or even damage the encoder. **Comprehensive tests of the entire system are required.**
- **Shock**
  The encoders are qualified on a test stand to operate with the specified acceleration values and duration in accordance with EN 60068-2-27. This does not include **permanent shock loads**, which **must be tested in the application.**
- The **maximum angular acceleration** is 10^5 rad/s^2 (DIN 32878). This is the highest permissible acceleration at which the rotor will rotate without damage to the encoder. The angular acceleration actually attainable depends on the shaft connection. A sufficient safety factor is to be determined through system tests.

Humidity
The max. permissible relative humidity is 75%. 95% is permissible temporarily. Condensation is not permissible.

Magnetic fields
Magnetic fields > 30 mT can impair the proper function of encoders. If required, please contact HEIDENHAIN, Traunreut.

RoHS
HEIDENHAIN has tested the products for harmlessness of the materials as per European Directives 2002/95/EC (RoHS) and 2002/96/EC (WEEE). For a Manufacturer Declaration on RoHS, please refer to your sales agency.

Natural frequencies
The rotor and the couplings of ROC/ROQ/ROD and RIC/RIQ rotary encoders, as also the stator and stator coupling of ECN/EQN/ERN rotary encoders, form a single vibrating spring-mass system.
The **natural frequency f_N** should be as high as possible. A prerequisite for the highest possible natural frequency on **ROC/ROQ/ROD rotary encoders** is the use of a diaphragm coupling with a high torsional rigidity C (see *Shaft Couplings*).

$$f_N = \frac{1}{2 \cdot \pi} \cdot \sqrt{\frac{C}{I}}$$

f_N: Natural frequency in Hz
C: Torsional rigidity of the coupling in Nm/rad
I: Moment of inertia of the rotor in kgm^2

ECN/EQN/ERN rotary encoders with their stator couplings form a vibrating spring-mass system whose **natural frequency f_N** should be as high as possible. If radial and/or axial acceleration forces are added, the stiffness of the encoder bearings and the encoder stators are also significant. If such loads occur in your application, HEIDENHAIN recommends consulting with the main facility in Traunreut.

Protection against contact (EN 60529)
After encoder installation, all rotating parts must be protected against accidental contact during operation.

Protection (EN 60529)
The degree of protection shown in the catalog is adapted to the usual mounting conditions. You will find the respective values in the Specifications. If the given degree of protection is not sufficient (such as when the encoders are mounted vertically), the encoders should be protected by suited measures such as covers, labyrinth seals, or other methods. Splash water must not contain any substances that would have harmful effects on the encoder parts.

Expendable parts
Encoders from HEIDENHAIN are designed for a long service life. Preventive maintenance is not required. They contain components that are subject to wear, depending on the application and manipulation. These include in particular moving cables.
On encoders with integral bearing, other such components are the bearings, shaft sealing rings on rotary and angle encoders, and sealing lips on sealed linear encoders.

System tests
Encoders from HEIDENHAIN are usually integrated as components in larger systems. Such applications require **comprehensive tests of the entire system** regardless of the specifications of the encoder.

The specifications given in the brochure apply to the specific encoder, not to the complete system. Any operation of the encoder outside of the specified range or for any other than the intended applications is at the user's own risk. In safety-related systems, the higher-level system must verify the position value of the encoder after switch-on.

Mounting
Work steps to be performed and dimensions to be maintained during mounting are specified solely in the mounting instructions supplied with the unit. All data in this catalog regarding mounting are therefore provisional and not binding; they do not become terms of a contract.

Changes to the encoder
The correct operation and accuracy of encoders from HEIDENHAIN is ensured only if they have not been modified. Any changes, even minor ones, can impair the operation and reliability of the encoders, and result in a loss of warranty. This also includes the use of additional retaining compounds, lubricants (e.g. for screws) or adhesives not explicitly prescribed. In case of doubt, we recommend contacting HEIDENHAIN in Traunreut.

Temperature ranges

For the unit in its packaging, the **storage temperature range** is –30 to 80 °C. The **operating temperature range** indicates the temperatures the encoder may reach during operation in the actual installation environment. The function of the encoder is guaranteed within this range (DIN 32878). The operating temperature is measured on the face of the encoder flange (see dimension drawing) and must not be confused with the ambient temperature.

The temperature of the encoder is influenced by:
• Mounting conditions
• The ambient temperature
• Self-heating of the encoder

The self-heating of an encoder depends both on its design characteristics (stator coupling/solid shaft, shaft sealing ring, etc.) and on the operating parameters (rotational speed, power supply). Temporarily increased self-heating can also occur after very long breaks in operation (of several months). Please take a two-minute run-in period at low speeds into account. Higher heat generation in the encoder means that a lower ambient temperature is required to keep the encoder within its permissible operating temperature range.

These tables show the approximate values of self-heating to be expected in the encoders. In the worst case, a combination of operating parameters can exacerbate self-heating, for example a 30 V power supply and maximum rotational speed. Therefore, the actual operating temperature should be measured directly at the encoder if the encoder is operated near the limits of permissible parameters. Then suitable measures should be taken (fan, heat sinks, etc.) to reduce the ambient temperature far enough so that the maximum permissible operating temperature will not be exceeded during continuous operation.

For high speeds at maximum permissible ambient temperature, special versions are available on request with reduced degree of protection (without shaft seal and its concomitant frictional heat).

Self-heating at supply voltage	15 V	30 V
ERN/ROD	Approx. + 5 K	Approx. +10 K
ECN/EQN/ROC/ROQ	Approx. + 5 K	Approx. +10 K

Heat generation at speed n_{max}		
Solid shaft **ROC/ROQ/ROD**		Approx. + 5 K with IP 64 protection Approx. + 10 K with IP 66 protection
Blind hollow shaft **ECN/EQN/ERN 400**		Approx. + 30 K with IP 64 protection Approx. + 40 K with IP 66 protection
ECN/EQN/ERN 1000		Approx. +10 K
Hollow through shaft **ECN/ERN 100** **ECN/EQN/ERN 400**		Approx. + 40 K with IP 64 protection Approx. + 50 K with IP 66 protection

An encoder's typical self-heating values depend on its design characteristics at maximum permissible speed. The correlation between rotational speed and heat generation is nearly linear.
Measuring the actual operating temperature at the defined measuring point of the rotary encoder (see *Specifications*)

Interfaces
Incremental Signals 〰 1 V$_{PP}$

HEIDENHAIN encoders with 〰 1 V$_{PP}$ interface provide voltage signals that can be highly interpolated.

The sinusoidal **incremental signals** A and B are phase-shifted by 90° elec. and have an amplitude of typically 1 V$_{PP}$. The illustrated sequence of output signals—with B lagging A—applies for the direction of motion shown in the dimension drawing.

The **reference mark signal** R has a usable component G of approx. 0.5 V. Next to the reference mark, the output signal can be reduced by up to 1.7 V to a quiescent level H. This must not cause the subsequent electronics to overdrive. Even at the lowered signal level, signal peaks with the amplitude G can also appear.

The data on **signal amplitude** apply when the power supply given in the specifications is connected to the encoder. They refer to a differential measurement at the 120 ohm terminating resistor between the associated outputs. The signal amplitude decreases with increasing frequency. The **cutoff frequency** indicates the scanning frequency at which a certain percentage of the original signal amplitude is maintained:
- −3 dB ≙ 70 % of the signal amplitude
- −6 dB ≙ 50 % of the signal amplitude

The data in the signal description apply to motions at up to 20% of the −3 dB cutoff frequency.

Interpolation/resolution/measuring step
The output signals of the 1-V$_{PP}$ interface are usually interpolated in the subsequent electronics in order to attain sufficiently high resolutions. For **velocity control,** interpolation factors are commonly over 1000 in order to receive usable velocity information even at low speeds.

Measuring steps for **position measurement** are recommended in the specifications. For special applications, other resolutions are also possible.

Short-circuit stability
A temporary short circuit of one signal output to 0 V or U$_P$ (except encoders with U$_{Pmin}$ = 3.6 V) does not cause encoder failure, but it is not a permissible operating condition.

Short circuit at	20 °C	125 °C
One output	< 3 min	< 1 min
All outputs	< 20 s	< 5 s

Interface	Sinusoidal voltage signals 〰 **1 V$_{PP}$**
Incremental signals	**2 nearly sinusoidal signals A and B**
	Signal amplitude M: 0.6 to 1.2 V$_{PP}$; typically 1 V$_{PP}$
	Asymmetry |P – N|/2M: ≤ 0.065
	Amplitude ratio M$_A$/M$_B$: 0.8 to 1.25
	Phase angle |φ1 + φ2|/2: 90° ± 10° elec.
Reference-mark signal	**One or several signal peaks R**
	Usable component G: ≥ 0.2 V
	Quiescent value H: ≤ 1.7 V
	Switching threshold E, F: 0.04 to 0.68 V
	Zero crossovers K, L: 180° ± 90° elec.
Connecting cables	Shielded HEIDENHAIN cable
	PUR [4(2 x 0.14 mm^2) + (4 x 0.5 mm^2)]
Cable length	Max. 150 m with 90 pF/m distributed capacitance
Propagation time	6 ns/m

These values can be used for dimensioning of the subsequent electronics. Any limited tolerances in the encoders are listed in the specifications. For encoders without integral bearing, reduced tolerances are recommended for initial operation (see the mounting instructions).

Interfaces
Incremental Signals ⊓⊔TTL

HEIDENHAIN encoders with ⊓⊔TTL interface incorporate electronics that digitize sinusoidal scanning signals with or without interpolation.

The **incremental signals** are transmitted as the square-wave pulse trains U_{a1} and U_{a2}, phase-shifted by 90° elec. The **reference mark signal** consists of one or more reference pulses U_{a0}, which are gated with the incremental signals. In addition, the integrated electronics produce their **inverted signals** $\overline{U_{a1}}$, $\overline{U_{a2}}$ and $\overline{U_{a0}}$ for noise-proof transmission. The illustrated sequence of output signals—with U_{a2} lagging U_{a1}—applies to the direction of motion shown in the dimension drawing.

The **fault-detection signal** $\overline{U_{aS}}$ indicates fault conditions such as breakage of the power line or failure of the light source. It can be used for such purposes as machine shut-off during automated production.
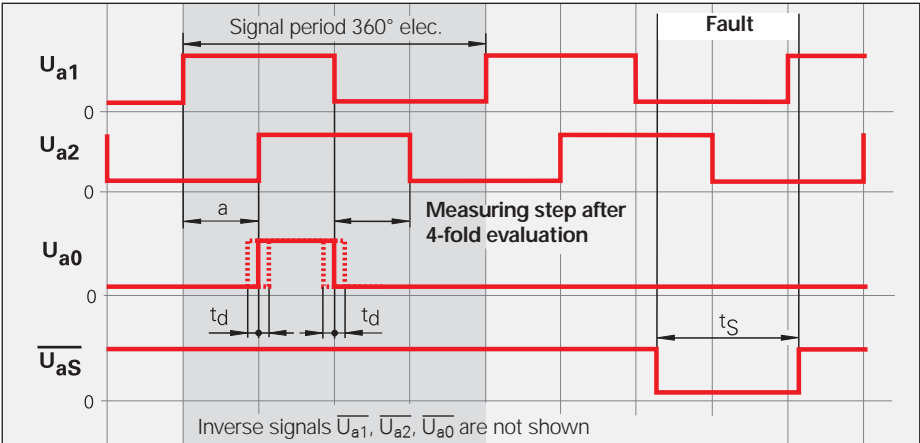

The distance between two successive edges of the incremental signals U_{a1} and U_{a2} through 1-fold, 2-fold or 4-fold evaluation is one **measuring step.**

The subsequent electronics must be designed to detect each edge of the square-wave pulse. The minimum **edge separation a** listed in the *Specifications* applies to the illustrated input circuitry with a cable length of 1 m, and refers to a measurement at the output of the differential line receiver. Propagation-time differences in cables additionally reduce the edge separation by 0.2 ns per meter of cable length. To prevent counting errors, design the subsequent electronics to process as little as 90 % of the resulting edge separation.

The max. permissible **shaft speed** or **traversing velocity** must never be exceeded.

The permissible **cable length** for transmission of the TTL square-wave signals to the subsequent electronics depends on the edge separation a. It is at most 100 m, or 50 m for the fault detection signal. This requires, however, that the power supply (see *Specifications*) be ensured at the encoder. The sensor lines can be used to measure the voltage at the encoder and, if required, correct it with an automatic control system (remote sense power supply).

Interface	Square-wave signals ⊓⊔TTL

Interfaces
Commutation Signals for Sinusoidal Commutation

The **commutation signals C and D** are taken from the so-called Z1 track and form one sine or cosine period per revolution. They have a signal amplitude of typically 1 V_{PP} at 1 kΩ. The input circuitry of the subsequent electronics is the same as for the $\sim$ 1 V_{PP} interface. The required terminating resistor of Z_0 however, is 1 kΩ instead of 120 Ω.

The **ERN 1185** and **ERN 1387** are rotary encoders with commutation signals for sinusoidal commutation.

Interfaces
Absolute Position Values EnDat

The EnDat interface is a digital, **bidirectional** interface for encoders. It is capable both of transmitting **position values** as well as transmitting or updating information stored in the encoder, or saving new information. Thanks to the **serial transmission method**, only **four signal lines** are required. The data is transmitted in **synchronism** with the clock signal from the subsequent electronics. The type of transmission (position values, parameters, diagnostics, etc.) is selected through mode commands that the subsequent electronics send to the encoder. Some functions are available only with EnDat 2.2 mode commands.

For more information, refer to the *EnDat* Technical Information sheet or visit *www.endat.de.*

Position values can be transmitted with or without additional information (e.g. position value 2, temperature sensors, diagnostics, limit position signals).
Besides the position, additional information can be interrogated in the closed loop and functions can be performed with the EnDat 2.2 interface.

Parameters are saved in various memory areas, e.g.:
• Encoder-specific information
• Information of the OEM (e.g. "electronic ID label" of the motor)
• Operating parameters (datum shift, instructions, etc.)
• Operating status (alarm or warning messages)

Monitoring and diagnostic functions of the EnDat interface make a detailed inspection of the encoder possible.
• Error messages
• Warnings
• Online diagnostics based on valuation numbers (EnDat 2.2)

Incremental signals
EnDat encoders are available with or without incremental signals. EnDat 21 and EnDat 22 encoders feature a high internal resolution. An evaluation of the incremental signal is therefore unnecessary.

Clock frequency and cable length
The clock frequency is variable—depending on the cable length (max. 150 m)—between **100 kHz** and **2 MHz.** With propagation-delay compensation in the subsequent electronics, clock frequencies up to **16 MHz** at cable lengths up to 100 m are possible.

Cables and Connecting Elements
Cables inside the Motor Housing

Encoder cables in the motor housing usually have a sheathing of a special elastomer (EPG). They are resistant to oil in accordance with VDE 0472 (Part 803/test type B) and to hydrolysis in accordance with VDE 0282 (Part 10). They are free of silicone and halogens. In comparison with PUR cables, EPG cables are only conditionally resistant to media, frequent flexing and continuous torsion. In rigid configuration they can be used at up to 120 °C.

General Electrical Information
For Rotary Encoders for Electrical Drives

Temperature measurement in motors

In order to protect a motor from an excessive load, the motor manufacturer usually installs a temperature sensor near the motor coil. In classic applications, the values from the temperature sensor are led via two separate lines to the subsequent electronics, where they are evaluated. With HEIDENHAIN encoders for servo drives, the temperature sensor can be connected to the encoder cable inside the motor housing, and the values transmitted via the encoder cable. This means that no separate lines from the motor to the drive controller are necessary.

Integrated temperature evaluation

Besides the integrated temperature sensor (accuracy approx. ± 4 K at 125 °C), encoders with EnDat 22 interface also permit connection of an external temperature sensor (not with ECI 1118). The encoder also evaluates the external sensor signal. The digitized temperature value is transmitted purely serially via the EnDat interface as additional information.

Please note:
- The transmitted temperature value is not a safe value in the sense of functional safety.
- The encoder temperature range permitted at the measuring point on the flange must be complied with independently of the temperature values transmitted over the EnDat interface.

Connectable temperature sensors

The temperature evaluation within the rotary encoder is designed for a KTY 84-130 PTC thermistor. If other temperature sensors are used, then the temperature must be converted according to the resistance curve. In the example shown, the temperature of 200 °C reported via the EnDat interface is actually 100 °C if a KTY 83-110 is used as temperature sensor.

Information for the connection of an external temperature sensor
- Only connect passive temperature sensors
- Only use temperature sensors with double or reinforced insulation
- No galvanic separation of the sensor input in the electronics of the rotary encoder
- The accuracy of the temperature measurement depends on the temperature range:
  – Approx. ± 3 K at –40 °C to 160 °C
  – Approx. ± 20 K at ≤ –40 °C
  – Approx. ± 50 K at ≥ 160 °C
Correlation between the temperature and resistance value for KTY 84-130, with conversion example to KTY 83-110

General Electrical Information

Power supply

Connect HEIDENHAIN encoders only to subsequent electronics whose power supply is generated from PELV systems **(EN 50178)**. In addition, overcurrent protection and overvoltage protection are required in safety-related applications.

If HEIDENHAIN encoders are to be operated in accordance with IEC 61010-1, power must be supplied from a secondary circuit with current or power limitation as per IEC 61010-1:2001, section 9.3 or IEC 60950-1:2005, section 2.5 or a Class 2 secondary circuit as specified in UL1310.

The encoders require a **stabilized DC voltage U_P** as power supply. The respective *Specifications* state the required power supply and the current consumption. The permissible ripple content of the DC voltage is:
- High frequency interference $U_{PP} < 250$ mV with $dU/dt > 5$ V/µs
- Low frequency fundamental ripple $U_{PP} < 100$ mV

The values apply as measured at the encoder, i.e., without cable influences. The voltage can be monitored and adjusted with the encoder's **sensor lines.** If a controllable power supply is not available, the voltage drop can be halved by switching the sensor lines parallel to the corresponding power lines.

Calculation of the **voltage drop**:

$$\Delta U = 2 \cdot 10^{-3} \cdot \frac{1.05 \cdot L_C \cdot I}{56 \cdot A_P}$$

where
- ΔU: Voltage attenuation in V
- 1.05: Length factor due to twisted wires
- L_C: Cable length in m
- I: Current consumption in mA
- A_P: Cross section of power lines in mm^2

The voltage actually applied to the encoder is to be considered when **calculating the encoder's power requirement**. This voltage consists of the supply voltage U_P provided by the subsequent electronics minus the line drop at the encoder. For encoders with an expanded supply range, the voltage drop in the power lines must be calculated under consideration of the nonlinear current consumption (see next page).

If the voltage drop is known, all parameters for the encoder and subsequent electronics can be calculated, e.g. voltage at the encoder, current requirements and power consumption of the encoder, as well as the power to be provided by the subsequent electronics.

Switch-on/off behavior of the encoders

The output signals are valid no sooner than after switch-on time $t_{SOT} = 1.3$ s (2 s for PROFIBUS-DP) (see diagram). During time t_{SOT} they can have any levels up to 5.5 V (with HTL encoders up to U_{Pmax}). If an interpolation electronics unit is inserted between the encoder and the power supply, this unit's switch-on/off characteristics must also be considered. If the power supply is switched off, or when the supply voltage falls below U_{min}, the output signals are also invalid. During restart, the signal level must remain below 1 V for the time t_{SOT} before power on. These data apply to the encoders listed in the catalog—customer-specific interfaces are not included.

Encoders with new features and increased performance range may take longer to switch on (longer time t_{SOT}). If you are responsible for developing subsequent electronics, please contact HEIDENHAIN in good time.

Isolation

The encoder housings are isolated against internal circuits.
Rated surge voltage: 500 V
(preferred value as per VDE 0110 Part 1, overvoltage category II, contamination level 2)

Transient response of supply voltage and switch-on/switch-off behavior
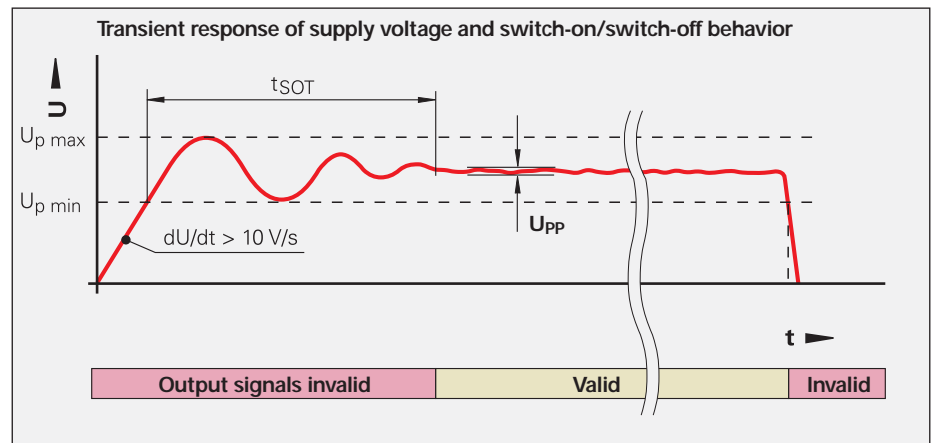

Cable	Cross section of power supply lines A_P

[5] Also Fanuc, Mitsubishi [6] Adapter cables for RCN, LC

Encoders with expanded voltage supply range

For encoders with expanded supply voltage range, the current consumption has a nonlinear relationship with the supply voltage. On the other hand, the power consumption follows a linear curve (see *Current and power consumption* diagram). The maximum power consumption at minimum and maximum supply voltage is listed in the **Specifications**. The power consumption at maximum supply voltage (worst case) accounts for:

• Recommended receiver circuit
• Cable length 1 m
• Age and temperature influences
• Proper use of the encoder with respect to clock frequency and cycle time

The typical current consumption at no load (only supply voltage is connected) for 5 V supply is specified.

The actual power consumption of the encoder and the required power output of the subsequent electronics are measured while taking the voltage drop on the supply lines in four steps:

Step 1: Resistance of the supply lines
The resistance values of the power lines (adapter cable and encoder cable) can be calculated with the following formula:

$$R_L = 2 \cdot \frac{1.05 \cdot L_C \cdot I}{56 \cdot A_P}$$

Step 2: Coefficients for calculation of the drop in line voltage

$$b = -R_L \cdot \frac{P_{Emax} - P_{Emin}}{U_{Emax} - U_{Emin}} - U_P$$

$$c = P_{Emin} \cdot R_L + \frac{P_{Emax} - P_{Emin}}{U_{Emax} - U_{Emin}} \cdot R_L \cdot (U_P - U_{Emin})$$

Step 3: Voltage drop based on the coefficients b and c

$$\Delta U = -0.5 \cdot (b + \sqrt{b^2 - 4 \cdot c})$$

Where:

U_{Emax}, U_{Emin}: Minimum or maximum supply voltage of the encoder in V

P_{Emin}, P_{Emax}: Maximum power consumption at minimum or maximum power supply, respectively, in W

U_S: Supply voltage of the subsequent electronics in V

Step 4: Parameters for subsequent electronics and the encoder
Voltage at encoder:
$$U_E = U_P - \Delta U$$

Current requirement of encoder:
$$I_E = \Delta U / R_L$$

Power consumption of encoder:
$$P_E = U_E \cdot I_E$$

Power output of subsequent electronics:
$$P_S = U_P \cdot I_E$$

R_L: Cable resistance (for both directions) in ohms

ΔU: Voltage drop in the cable in V

1.05: Length factor due to twisted wires

L_C: Cable length in m

A_P: Cross section of power lines in mm^2

Influence of cable length on the power output of the subsequent electronics (example representation)

	Encoder cable/adapter cable	Connecting cables	Total
1	3 m	/	3 m
2	20 m	/	20 m
3	3 m	17 m	20 m
4	3 m	47 m	50 m
5	3 m	97 m	100 m
Current and power consumption with respect to the supply voltage (example representation)

— Power consumption of encoder (normalized to value at 5 V)

— Current requirement of encoder (normalized to value at 5 V)
Electrically permissible speed/ traversing speed

The maximum permissible shaft speed or traversing velocity of an encoder is derived from
- the **mechanically** permissible shaft speed/traversing velocity (if listed in the *Specifications*)
  and
- the **electrically** permissible shaft speed/ traversing velocity.
  For encoders with **sinusoidal output signals**, the electrically permissible shaft speed/traversing velocity is limited by the –3dB/ –6dB cutoff frequency or the permissible input frequency of the subsequent electronics.
  For encoders with **square-wave signals,** the electrically permissible shaft speed/ traversing velocity is limited by
  – the maximum permissible scanning frequency f_{max} of the encoder
    and
  – the minimum permissible edge separation a for the subsequent electronics.

For angular or rotary encoders

$$n_{max} = \frac{f_{max}}{z} \cdot 60 \cdot 10^3$$

For linear encoders

$$v_{max} = f_{max} \cdot SP \cdot 60 \cdot 10^{-3}$$

Where:
- n_{max}: Elec. permissible speed in min^{-1}
- v_{max}: Elec. permissible traversing velocity in m/min
- f_{max}: Max. scanning/output frequency of encoder or input frequency of subsequent electronics in kHz
- z: Line count of the angle or rotary encoder per 360 °
- SP: Signal period of the linear encoder in µm

Cable

For safety-related applications, use HEIDENHAIN cables and connectors.

Versions
The cables of almost all HEIDENHAIN encoders and all adapter and connecting cables are sheathed in **polyurethane (PUR cable).** Most adapter cables for within motors and a few cables on encoders are sheathed in a **special elastomer (EPG cable).** These cables are identified in the specifications or in the cable tables with " EPG."

Durability
PUR cables are resistant to oil and hydrolysis in accordance with **VDE 0472** (Part 803/test type B) and resistant to microbes in accordance with **VDE 0282** (Part 10). They are free of PVC and silicone and comply with UL safety directives. The **UL certification** AWM STYLE 20963 80 °C 30 V E63216 is documented on the cable.

EPG cables are resistant to oil in accordance with **VDE 0472** (Part 803/test type B) and to hydrolysis in accordance with **VDE 0282** (Part 10). They are free of silicone and halogens. In comparison with PUR cables, they are only conditionally resistant to media, frequent flexing and continuous torsion.
Temperature range
HEIDENHAIN cables can be used for
Rigid configuration (PUR)   –40 to   80 °C
Rigid configuration (EPG)   –40 to 120 °C
Frequent flexing (PUR)   –10 to   80 °C

PUR cables with limited resistance to hydrolysis and microbes are rated for up to 100 °C. If needed, please ask for assistance from HEIDENHAIN Traunreut.

Lengths
The **cable lengths** listed in the *Specifications* apply only for HEIDENHAIN cables and the recommended input circuitry of subsequent electronics.

Cable	Bend radius R	
	Rigid configuration	**Frequent flexing**
Ø 3.7 mm	≥ 8 mm	≥ 40 mm
Ø 4.3 mm	≥ 10 mm	≥ 50 mm
Ø 4.5 mm EPG	≥ 18 mm	–
Ø 4.5 mm **Ø 5.1 mm**	≥ 10 mm	≥ 50 mm
Ø 6 mm **Ø 10 mm**[1]	≥ 20 mm ≥ 35 mm	≥ 75 mm ≥ 75 mm
Ø 8 mm **Ø 14 mm**[1]	≥ 40 mm ≥ 100 mm	≥ 100 mm ≥ 100 mm

[1] Metal armor

Noise-free signal transmission

Electromagnetic compatibility/ CE compliance

When properly installed, and when HEIDENHAIN connecting cables and cable assemblies are used, HEIDENHAIN encoders fulfill the requirements for electromagnetic compatibility according to 2004/108/EC with respect to the generic standards for:

- **Noise immunity EN 61000-6-2:**
  Specifically:
  - ESD   EN 61000-4-2
  - Electromagnetic fields   EN 61000-4-3
  - Burst   EN 61000-4-4
  - Surge   EN 61000-4-5
  - Conducted disturbances EN 61000-4-6
  - Power frequency magnetic fields   EN 61000-4-8
  - Pulse magnetic fields   EN 61000-4-9
- **Interference EN 61000-6-4:**
  Specifically:
  - For industrial, scientific and medical equipment (ISM)   EN 55011
  - For information technology equipment   EN 55022

Transmission of measuring signals— electrical noise immunity

Noise voltages arise mainly through capacitive or inductive transfer. Electrical noise can be introduced into the system over signal lines and input or output terminals.
Possible sources of noise include:
- Strong magnetic fields from transformers, brakes and electric motors
- Relays, contactors and solenoid valves
- High-frequency equipment, pulse devices, and stray magnetic fields from switch-mode power supplies
- AC power lines and supply lines to the above devices

Protection against electrical noise

The following measures must be taken to ensure disturbance-free operation:
- Use only original HEIDENHAIN cables. Consider the voltage attenuation on supply lines.
- Use connecting elements (such as connectors or terminal boxes) with metal housings. Only the signals and power supply of the connected encoder may be routed through these elements. Applications in which additional signals are sent through the connecting element require specific measures regarding electrical safety and EMC.

- Connect the housings of the encoder, connecting elements and subsequent electronics through the shield of the cable. Ensure that the shield has complete contact over the entire surface (360°). For encoders with more than one electrical connection, refer to the documentation for the respective product.
- For cables with multiple shields, the inner shields must be routed separately from the outer shield. Connect the inner shield to 0 V of the subsequent electronics. Do not connect the inner shields with the outer shield, neither in the encoder nor in the cable.
- Connect the shield to protective ground as per the mounting instructions.
- Prevent contact of the shield (e.g. connector housing) with other metal surfaces. Pay attention to this when installing cables.
- Do not install signal cables in the direct vicinity of interference sources (inductive consumers such as contacts, motors, frequency inverters, solenoids, etc.).
  – Sufficient decoupling from interference-signal-conducting cables can usually be achieved by an air clearance of 100 mm or, when cables are in metal ducts, by a grounded partition.
  – A minimum spacing of 200 mm to inductors in switch-mode power supplies is required.
- If compensating currents are to be expected within the overall system, a separate equipotential bonding conductor must be provided. The shield does not have the function of an equipotential bonding conductor.
- Only provide power from PELV systems **(EN 50178) to position encoders.** Provide high-frequency grounding with low impedance **(EN 60204-1 Chap. EMC)**.
- For encoders with 11 µA$_{PP}$ interface: For extension cables, use only HEIDENHAIN cable ID 244955-01. Overall length: max. 30 m.
Minimum distance from sources of interference

HEIDENHAIN Measuring Equipment
For Incremental Encoders

PWM 9 is a universal measuring device for checking and adjusting HEIDENHAIN incremental encoders. There are different expansion modules available for checking the different encoder signals. The values can be read on an LCD monitor. Soft keys provide ease of operation.

	PWM 9
Inputs	Expansion modules (interface boards) for 11 µA$_{PP}$; 1 V$_{PP}$; TTL; HTL; EnDat*/SSI*/commutation signals *No display of position values or parameters
Functions	• **Measures** signal amplitudes, current consumption, operating voltage, scanning frequency • **Graphically displays** incremental signals (amplitudes, phase angle and on-off ratio) and the reference-mark signal (width and position) • **Displays symbols** for the reference mark, fault detection signal, counting direction • **Universal counter,** interpolation selectable from single to 1 024-fold • **Adjustment support** for exposed linear encoders
Outputs	• Inputs are connected through to the subsequent electronics • BNC sockets for connection to an oscilloscope
Power supply	DC 10 to 30 V, max. 15 W
Dimensions	150 mm × 205 mm × 96 mm

For Absolute Encoders

HEIDENHAIN offers an **adjusting and testing package** for diagnosis and adjustment of HEIDENHAIN encoders with absolute interface.
• **IK 215** PC expansion board
• **ATS** adjusting and testing software

	IK 215
Encoder input	• EnDat 2.1 or EnDat 2.2 (absolute value with/without incremental signals) • FANUC serial interface • Mitsubishi High Speed Serial Interface • SSI
Interface	PCI bus, Rev. 2.1
System requirements	• Operating system: Windows XP (Vista upon request) • Approx. 20 MB free space on the hard disk
Signal subdivision for incremental signals	Up to 65 536-fold
Dimensions	100 mm x 190 mm

	ATS
Languages	Choice between English or German
Functions	• Position display • Connection dialog • Diagnostics • Mounting wizard for ECI/EQI • Additional functions (if supported by the encoder) • Memory contents

Evaluation Electronics

IK 220
Universal PC counter card
The IK 220 is an expansion board for PCs for recording the measured values of two incremental or absolute linear or angle encoders. The subdivision and counting electronics subdivide the sinusoidal input signals up to 4096-fold. A driver software package is included in delivery.

For more information, see the *IK 220* Product Information document as well as the Product Overview of *Interface Electronics.*

	IK 220			
Input signals (switchable)	$\sim$ 1 V$_{PP}$	$\sim$ 11 µA$_{PP}$	EnDat 2.1	SSI
Encoder inputs	Two D-sub connections (15-pin) male			
Input frequency	≤ 500 kHz	≤ 33 kHz	–	
Cable length	≤ 60 m		≤ 50 m	≤ 10 m
Signal subdivision (signal period : meas. step)	Up to 4096-fold			
Data register for measured values (per channel)	48 bits (44 bits used)			
Internal memory	For 8192 position values			
Interface	PCI bus			
Driver software and demonstration program	**For Windows 98/NT/2000/XP** in VISUAL C++, VISUAL BASIC and BORLAND DELPHI			
Dimensions	Approx. 190 mm × 100 mm			

Windows is a registered trademark of the Microsoft Corporation.
